* Strains of Type IV isolated in the United States did not have the 6 fraction but usually agglutinated in the 3 and 4 group sera

METHODS

Antisera were prepared by injecting rabbits with formalinized (0.3 per cent) broth cultures at 5-7 day intervals in increasing doses until satisfactory agglutinin titers were reached (3-5 injections). *S. dysenteriae* were washed before injection. When titers of 1:5,120 or higher were reached or when no further increase occurred after additional injections the animals were bled and the serum preserved with 0.5 per cent phenol or by desiccation by the lyophile process.

Antigens for the slide test were made by suspending the growth from 18-24 hour agar slants in formalinized saline (0.3 per cent) and adjusting the density approximately to Gates 1.0. With most cultures of *S. alkaescens* it was necessary to heat the antigen at 60-70° C. for 1 hour before agglutination would occur. Since this degree of heating did not affect reactions of the other *Shigella* strains studied it was done as a routine procedure with all types.

The slide tests were performed on 5-7 in. glass slides divided by paraffin markings into sections approximately 1 x 2.5 cm. A total of 72 tests could be made on one slide. Paraffin rings as made for the syphilis slide tests (Mazzini, Kline) are also satisfactory. Equal quantities (about 0.02 ml.) of serum and antigen are added to the square, mixed, agitated mechanically or by hand with a rotary-rocking motion for 2 minutes, and then the degree of agglutination is read.

Standardization of the antisera must be done before they can be used for typing. *S. dysenteriae*, *S. ambigua*, *S. sonnei*, *S. alkaescens*, and the pooled sera were used without adsorption but in dilution sufficient to eliminate the minor cross-reactions as shown by tests with representative organisms of all the types. In each of the pooled paradyntery sera six types were included.

The typing fluids were made by combining the individual sera and diluting according to titer. Final dilutions in the mixture varied from 1:10 to 1:100.

Type- and group-specific typing fluids were prepared by adsorption with appropriate cultures as indicated in Tables 1 and 2. Sera were adsorbed at 37° C. in 1:5 or 1:10 dilution with formalinized culture until the reactions of the adsorbed sera were specific. The completed typing fluids were preserved with 0.5 per cent phenol.

Methods employed in the Bureau of Laboratories for the isolation of enteric pathogens have been outlined previously.² SS agar and MacConkey's agar are used for isolation of *S. paradynteriae* and *S. sonnei* strains. The classification of the organisms as determined by the agglutination test should be confirmed by fermentation reactions.

RESULTS

A summary of the cultures examined is presented in Table 3. Included in the total figures are stock collection strains received from a number of sources as well as recently isolated cultures of most of the types. The strains isolated in Connecticut and studied at the Bureau of Laboratories of the Connecticut State Department of Health since 1940 are listed separately to show the incidence of the various types in this locality.

Seventeen strains of *S. dysenteriae* have been identified by the slide test although none were isolated in Connecticut. Five cultures of *S. ambigua* were typed including one from a Connecticut case. The majority of strains were in the Flexner group, distributed among the I, II_a, II_b, III, IV, V, and VI varieties as indicated in the table. The frequency of Type III strains is high because of the large numbers isolated from one state institution where this type infection is endemic with occasional active outbreaks. If cultures

from this hospital are excluded the incidence of Type III cases was 27, or about the same as that for Types I, II_a, and II_b. One Type IV case was recently encountered within the state, and this type is present elsewhere in the United States since 8 strains received from Texas and 12 from Mississippi were identified as Type IV. One instance of Type V infection was recognized in Connecticut and one outbreak of Type VI (Newcastle) infection occurred from which ten isolations were made. Representatives of only two of the remaining Boyd types have been studied which were isolated in the United States. We identified ten strains of Type 170 and two of Type P274 isolated in Mississippi.

The incidence of *S. sonnei* types is high and 264 strains were identified of which about 90 per cent were isolated within the state. The figures for *S. alkalescens* does not represent the incidence of this species over the same time period since many strains that were isolated were not identified serologically.

A number of cultures which were

tentatively classified as dysentery organisms on the basis of biochemical reactions could not be typed by the diagnostic sera. Some of these have been subsequently classified in the paracolony group, but a number remain, which by physiological tests resemble the pathogenic *Shigella* types. The Eijkman and trimethylamine reactions of some of these strains have been determined and are negative, similar to *S. dysenteriae* and *S. paradysenteriae* cultures.^{12, 18} Some of these were mannitol-negative and may be like strains recently described by Sachs¹¹ isolated from cases of bacillary dysentery in India and Egypt. Other untyped strains were typical *S. paradysenteriae* as defined by *Bergey's Manual*, while some differed only by fermentation of xylose or dulcitol. Cultures identified by fermentation reactions as *S. ceylonensis* or *S. dispar* have not been included in Table 3.

DISCUSSION

The results show that satisfactory serological identification of the pathogenic *Shigella* organisms can be made

by the slide test. The test is not as complex as might be assumed. The procedure outlined uses 16 or 17 immune sera for the entire group, but a great majority of the isolations could be identified with only 8 or 9 antisera. With the simple method of immunization the necessary antisera can be produced with little trouble. Titrations can be done in a short time, and the adsorption procedures for the preparation of type-specific and group sera are simple provided cultures of the proper antigenic structure are available. Antigens for the slide test are easily and quickly made and 1 ml. of typing fluid should be sufficient for nearly 50 tests. In our own laboratory we feel that the test is an excellent diagnostic aid. Furthermore, this method is similar to that used for *Salmonella* typing and can be incorporated into the routine procedure with little difficulty.

Strain identification in the detail that has been carried out may seem unnecessary and impractical at first thought. The majority of public health laboratories go only so far as to classify into the Flexner group, primarily because typing sera are not available. However, strain typing is essential if satisfactory epidemiology is to be done and detailed serological study is the only reliable means of typing. Occasionally a particular strain can be identified by its fermentative reactions; however, we have had strains of Type I, II_a, II_b, III, IV, and V which gave identical reactions in the usual differential media. Typing has been applied in the study of several small outbreaks of *S. paratyphosa* infection. For instance, during an outbreak of Type III infection in a state hospital three strains of Type II were found. Two were II_b and one was II_a. Follow-up of these cases showed that the two II_b types were new transfers to the building where the Type III outbreak occurred.

One was a recent admission to the hospital and the second had been associated with her for a short time in another section of the hospital. The Type II_a was isolated from an attendant. All three were unrelated to the active outbreak of Type III infection. Other instances similar to this have been encountered.

Boyd's scheme of labeling the paratyphosa strains has a number of advantages, and provides a good working basis for classification. The differentiation is based on the presence of the specific antigen, and X and Y strains are not considered as separate types. The common relationship through the group antigen is shown for the Flexner Types I through VI. If marked and consistent differences in group antigen among strains having the same type antigen are found, the strains can be identified by a subgrouping of the type as we have done for the W or II group. Inclusion of the Type 88 or Newcastle organism with the Flexner group appears justified on the basis of serological structure. It seems logical that greater weight should be placed on antigenic structure than on physiological properties. Varieties which differ in gas production or fermentation of mannitol or dulcitol as do the Manchester, Newcastle, and Type 88 strains⁶ can properly be considered as one type and included with the other Flexner organisms.

The essential differences between the types are the specific antigens, and therefore methods for typing should be concerned first of all with the detection of these type-specific antigens and secondarily with identification of the major group components. Methods utilizing unadsorbed sera and based on group reactions, such as that published recently by Hardy and associates,⁸ overlook this fundamental difference between types. The use of adsorbed sera is imperative if satisfactory dis-

inction is to be made between the type-specific and the group reactions. Furthermore, the various group components that are of differential value cannot be identified readily except by previous adsorptions of the antisera.

The possibility of loss of the type-specific antigen by variation to the group phase as described by Boyd has caused no difficulty in typing newly isolated Flexner cultures. On the other hand, it has been our experience that all of the newly isolated strains have contained some group antigen and the several group components could be identified in them. We have found variation in group components, however, particularly among the 103 strains. The 21 strains isolated in this country all have differed from the type culture since they did not have the principal 6 component of the type strain but agglutinated with the 3 and usually the 4 group antisera. This difference probably is a result of variation of the type strain.

Among the Flexner types we have found some biochemical differences which have correlated to a considerable degree with serological structure. Some of these seem worth mention. Type VI (Newcastle) and about 50 per cent of the II_a strains were the only indole-negative cultures encountered. Approximately two-thirds of the I and II_b strains, grown in 1 per cent tryptone broth, gave weak or trace reactions at 24 hours with Kovac's reagent and were negative with the Gnezda test. After 5-7 days' incubation, however, all gave distinct reactions by both tests. In contrast to all other types only 4 per cent of Type III strains fermented arabinose. The great majority of III cultures (97 per cent) fermented sorbitol, however, in contrast to the I, II, and IV strains which were uniformly negative. Reactions in sucrose, maltose, and rhamnose have been of no differential value.

On the basis of Boyd's findings we have included his additional types with the *S. paradysenteriae* group. They show little serological relationship to the Flexner types and some of them are slow fermenters of dulcitol or xylose. According to *Bergey's Manual* the xylose fermenting strains would be excluded from *S. paradysenteriae* species. However, they are similar in other characteristics and, considering their probable rôle in dysentery infection, should be included with the pathogenic paradysentery organisms. Furthermore, these strains resemble the other *S. paradysenteriae* in their Eijkman reaction and in their failure to reduce trimethylamine oxide.^{12, 18} As yet little information is available on the presence of these types in this country. A low incidence is expected since Types P288, D19 and P143 comprised a total of only 1.2 per cent of the 7,339 strains studied by Boyd.⁶ However, Type P274 has been reported in a food handler outbreak⁹ and we have identified strains of P274 and 170 types. Possibly the position of the Boyd strains should be left undefined for the present, but it seems probable that the scheme of labeling the Flexner types should be extended eventually to include the type-specific antigens of the additional Boyd strains.

It is impossible that any practical classification of the *Shigella* group will include all types since new ones will be encountered from time to time. In Table 3 a number of strains are listed which could not be classified by the present scheme. Some of these were old stock strains in which variation had doubtless occurred; possibly some of the others will subsequently turn out to be additional pathogenic types. It may be pertinent in this connection to suggest that a service for laboratory study of *Shigella* cultures somewhat like that rendered by Dr. P. R. Edwards at the National Sal-

monella Center for the *Salmonella* group, for instance, would meet a need that is felt often by public health laboratory workers.

Not infrequently, coliform and paracolon cultures have shown antigens in common with members of the *Shigella* group. Usually the reactions were minor and occurred with unadsorbed sera. We have also obtained agglutination of many of the paradysentery strains with certain *Salmonella* sera. These reactions have not been thoroughly investigated but the reciprocal reactions of *Salmonella* cultures in *S. paradysenteriae* antisera have usually been negative, and they could not be attributed to the type or group components that have been identified in the paradysentery organisms. Antigens similar to the *Salmonella* VI and XIII components have already been noted.⁴ A broad distribution of the antigens of *S. alkaescens* in coliform and paracolon types¹³ and in the P274 strain also occurs. Numerous and broad antigenic relationships have also been described for *Salmonella* organisms and other nonpathogenic types.^{3, 14} A similar overlapping of physiological characteristics has been pointed out between the various groups of the enteric organisms. The fact that organisms of the *Enterobacteriaceae* appear to be a continuous series of types without sharp demarcation either as to physiological or antigenic properties between the various sections, constitutes a problem to the "practical diagnostic bacteriologist." At present his best approach seems to be to use all available criteria for differentiation. Typical forms should offer little difficulty. It is up to him to recognize the atypical forms but the study of these can best be handled by the research laboratory.

SUMMARY

A method for serological identification of the pathogenic dysentery bac-

teria has been presented which utilizes a slide agglutination test employing formalinized antigens and titrated and adsorbed typing fluids. The test has the advantages of accuracy and speed, is similar to *Salmonella* typing methods, and can be readily incorporated into routine procedures.

Shigella organisms which have been identified by the slide test are *S. dysenteriae* (Shiga), *S. ambigua* (Schmitz), *S. paradysenteriae* (Flexner, Newcastle and Boyd types), *S. sonnei*, and *S. alkaescens*.

Within the paradysentery group, type identification is accomplished by the use of suitably adsorbed sera to show the type-specific antigens and certain group antigens of differential value. Type identification which can be done only by serological methods is essential for satisfactory epidemiological study.

The classification of the Flexner group proposed by Boyd in which V, W, and Z strains, Boyd Types 103 and P119, and the Newcastle organism have been designated as Types I through VI respectively on the basis of type-specific antigens provides a practical working basis for identification of the six types. It seems advisable to divide the II or W group into two sections since cultures have been encountered which had the same type-specific antigen but which were distinct epidemiologically and which exhibited marked differences in group components.

The Boyd Types 170, P288, P274, D1, D19, and P143 can be identified by their type-specific antigens. Some cultures have been encountered resembling pathogenic dysentery organisms which could not be classified into the recognized types by serological methods.

Results of the serological typings of 1,005 *Shigella* strains were presented. Strains isolated in Connecticut during a 3 year period included *S. ambigua*, *S. paradysenteriae* Types I, II_a, II_b, III, IV, V, and VI, *S. sonnei*, and *S.*

alkalescens. Strains of *S. paradysenteriae*, Boyd Types 170 and P274 were identified among cultures isolated in other parts of the United States.

ACKNOWLEDGMENT—We are indebted to Elizabeth Murphy and to E. K. Borman for assistance and suggestions during this work.

Nutrition: A Factor Important for Industrial Hygiene*

GEORGE R. COWGILL, PH.D.

Professor of Nutrition, Yale University, New Haven, Conn.

THE great developments in the science of nutrition over the past three decades have finally led to an appreciation of the importance of nutrition as a factor in industrial hygiene. We now accept the concept that health and efficiency can be affected by the *lack* of something from the food as well as the *presence* of a positive agent such as, for example, a machine that can injure a worker unless he is properly protected, air with too much dust in it, a noxious gas or food poison, a dangerous chemical that can cause injury when coming in contact with the skin, or a harmful microorganism.

At the beginning of this century it was generally believed that any combination of foods that furnished sufficient energy, protein, and important minerals like calcium and iron sufficed to nourish the body properly. If the student of nutrition should be asked in 1943 to list individually all the specific dietary factors known to be essential for health and well-being, he would cite approximately forty separate items. These could be classified under four headings:

1. Energy
2. Protein
3. Inorganic or mineral nutrients
4. Vitamins

* Presented at a Joint Session of the Industrial Hygiene, Food and Nutrition, and Public Health Nursing Sections of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 13, 1943.

This summary of the many food factors needed for health, admittedly very brief and perhaps open to criticism as constituting an oversimplification of an exceedingly complicated situation, is nevertheless to be emphasized here, because many industrialists, nutritionists, and students of public health and industrial hygiene have concentrated their attention too much on certain of these categories of interest, vitamins for example, and ignored the many others that are also important. These new developments have contributed to establishing the concept that health and efficiency can be affected by the *lack of something* in contrast to the *presence* of something—a negative rather than positive agent affecting health.

CURRENT INTEREST IN NUTRITION

The war and the need for tremendous industrial activity have compelled us to give more attention to this factor of diet in relation to industrial health. England, which has been much closer to the active theater of war, faced this problem long ago, and in 1939, through its government agencies, ruled that every industrial plant employing 250 or more workers should furnish at least one good meal per employee per day. Involved in this particular situation was, of course, the fact that a very large part of the food for the British Isles had to be received by shipment from

over the seas; it was necessary that this available food be properly rationed, and that the workers in industry be well fed in order to be able to turn out the instruments of war.

The Canadian Council on Nutrition¹ has adopted a set of recommendations concerning nutrition in industry that should be examined by all who would study this topic. Our own National Food Conference, held in May, 1941, recognized the importance of this problem and devoted a section to discussion of it. The National Research Council established a committee to study and advise concerning this question, and this committee has published a report² which merits the careful examination of all students of the subject. Two of the Councils of the American Medical Association have sponsored discussion of this topic at important national meetings.³ The American Association of Industrial Physicians and Surgeons has had a Committee on Nutrition in Industry, and this committee has been able to secure valuable information concerning prevailing industrial feeding practices. More recently there has appeared a very interesting and comprehensive document entitled *The Nutrition Front*, which is the report of the New York State Joint Legislative Committee on Nutrition.⁴ Finally, there should be mentioned the fact that the Nutrition and Food Conservation Branch of our federal Food Distribution Administration has an office in Washington that devotes itself to national aspects of this problem, and serves as a valuable source of information and guidance to all persons interested in this field of endeavor.

From what has just been cited it is evident that there has been a growing appreciation of the importance of insuring the health of the industrial worker as that health may be affected by food. As further evidence in support of this view one may cite the following passage from *Special Bulletin No. 12*,

issued by the U. S. Department of Labor in 1943⁵:

With plant after plant ranking dietary troubles high on their illness and absentee lists and with findings by the National Research Council that 71 per cent of workers' families have "poor" or "only fair" diets, the close relationship between nutrition and productivity needs no argument.

WHAT DO WE NEED TO KNOW?

In attempting to apply our modern knowledge of nutrition to industrial hygiene it is important that a body of pertinent scientific data be obtained. How are our industrial workers being fed at the present time? Can these feeding practices be improved? To what extent does malnutrition of one kind or another occur among industrial employees? If the incidence of such malnutrition is practically nil, one is certainly justified in questioning the wisdom of any elaborate program involving special measures of one kind or another which industry, or government, or both will have to implement by the establishment of special bureaus and for which large sums will have to be expended; if such malnutrition does exist, remedial measures of some kind are definitely in order. Are there any special industrial hazards for which one or more specific dietary factors, vitamins for example, are of demonstrated value? These are some of the questions that arise in any thoughtful consideration of the application of this modern knowledge of nutrition to industrial hygiene.

HOW ARE WORKERS BEING FED?

How are our industrial workers now being fed? It is a matter of common knowledge that the food situation is not the same in all parts of the country. The Stiebeling-Phipard⁶ study of 4,000 family dietaries collected in different sections of the country may be cited as suitable evidence for this statement. According to that study, pub-

lished in January, 1939, and therefore based on data collected prior to that date, the southern California area proved to be one of the best on account of its liberal supply of milk and milk products, citrus fruits, fresh colored vegetables, and meats.

Students of industrial hygiene might therefore suppose that because an industrial plant is located in a well fed area, the industrial workers in that plant will therefore be well fed. Unfortunately, this assumption has been proved to be erroneous, at least with respect to aircraft workers in one large plant in southern California^{7, 8} since 1939, the date the Stiebeling-Phipard study was published.

Time will not permit a detailed discussion of the findings at this plant. The dietary patterns described by Miss Wiehl⁷ no doubt reflected a situation resulting from the operation of many factors, such as a tremendous and sudden expansion of the plan on account of the war, a great influx of workers, a lack of concomitant development of suitable housing and eating facilities, and of course shortages of various foods in the area. Mere mention of these various factors, however, indicates how complicated many of the food situations in industry now are, and how many causes have operated to bring them about.

The point to be emphasized here is that students of industrial hygiene should first of all seek the facts regarding any feeding situation in question; when those facts have been collected, appropriate remedial measures can then, of course, be considered. The National Research Council's Committee on Nutrition in Industry has done all it can to foster this point of view, and has actively supported the research carried out in the aircraft plant in California under Dr. Borsook's direction with this end in mind: let us first of all *get the facts*. It is obvious that the prose-

cution of similar studies in other sections of the country is desirable, and efforts to organize such additional studies have been made; unfortunately such efforts have not been attended with much success for various reasons.

EATING FACILITIES IN PLANTS

Many industrial plants operate dining rooms, cafeterias, or other eating facilities. Examination of this situation reveals two separate problems. One concerns the operation of the facility, selection of the food to be served, supervision of its preparation and the like. Some of these facilities are well operated, being under the supervision of people trained in the science of nutrition and the application of that science in the handling of food; but even here it happens that a certain body of scientific facts is needed, pertaining particularly to the effect of various kitchen procedures on the nutritive values of the foods handled. Something is known about this topic but much desirable information remains as yet to be secured. It is known, for example, that much of the vitamin C is lost from the cabbage leaf when it is chopped up into fine pieces in making cole slaw, this loss being due to greater exposure of the cabbage cells to air. In the cooking of many foods appreciable amounts of vitamin B₁—thiamine—and other vitamins are lost; when the cooked product is allowed to stand for an appreciable period on the hot table from which it is served, further losses occur. This whole subject needs more extensive investigation; fortunately this needed additional work is already being carried on in various places, in large measure as part of coöperative research involving agricultural experiment stations and many other groups.

The problem just mentioned concerns the management of the eating facilities in plants. Although many such facilities are well operated, investigation has

revealed that many others are not; too often these others have been found to be supervised by persons with no special training in the science of nutrition, whose chief qualification has been that at some time or other they were able to serve a large number of meals at low cost. Students of industrial hygiene should be able to do something here in educating industrial managers to see the importance of securing qualified supervision of their plant operated eating facilities.

THE PROBLEM OF SELECTION OF FOOD

Even if these plant restaurants and the like are supervised by competent persons, we still have before us the problem of the worker himself, and how he selects food. The solution to this problem, in the last analysis, involves education of the employee in matters of food and nutrition. The management of the restaurant can assist in devious ways. For example, a combination of foods which makes an excellent lunch from the nutritive standpoint can be offered at a slightly lower cost than various popular but less valuable items would be if purchased singly. By this hidden device, so to speak, many workers can be encouraged to improve their selections by a subtle appeal to the pocketbook. The so-called "victory lunch" plan now used in many plants is based essentially on this idea.

Some facts have been collected in certain plants concerning the choices of foods made by employees passing down the cafeteria line. Trained nutritionists, able to rate the various selections, have reported interesting data. Food selections of course reflect food habits, family and racial backgrounds, and many other factors; and food habits are not easily changed. One authority once estimated that it took about thirty years of effort to change the food habits of the average Filipino sufficiently to

make him his own protector against the disease beriberi. The difficulty of the task of changing food habits should not cause us to despair, however.

At the present time, because of the war and its concomitant food shortages, the American people have become sensitized, so to speak, concerning the importance of nutrition and good food. Nutrition classes have been established in almost every community in the land. The Red Cross has undertaken most of this work. Many industrial organizations have also made notable contributions here, particularly those whose chief activity in peacetime is the manufacture of household appliances. These organizations have long employed as demonstrators people trained in home economics and related subjects; and more recently these employees have been utilized in various ways for this new kind of educational work extending not merely to all the employees of the home plant but to people outside as well.⁹ These efforts on the part of industry itself, special groups and communities, have been discussed elsewhere.

THE LUNCH-BOX AND NUTRITION

Many workers get their lunch from a lunch-box filled in the home. A recent survey by the State Health Department of Connecticut showed that by far the greater number of industrial establishments in that state had workers who brought their own lunch or who ate at restaurants, "hot-dog" stands and the like located in the vicinity of the plant. Only a relatively few very large plants presented situations that seemed to require special provision of food by the management. It seems evident that solution of the lunch-box problem must involve education of both the worker and his family concerning food values. An interesting attack on this problem is seen in the so-called Bridgeport Plan, a community effort organized and pushed by a local com-

mittee which includes in its personnel representatives of the medical profession, home economists, demonstrators employed by public utility concerns, and still other groups. This is a good illustration of what organized community effort can accomplish in this field.

THE PROBLEM OF THE CONCESSIONAIRE

Some industrial establishments offer to the employees food furnished by a concessionaire. This practice has been criticised by nutritionists on the ground that too often the concessionaire is interested merely in the profit to be made; he says he offers what the workers really want, and he cannot change their food habits. This may be true of many concessionaires, but I am able to find at least one concern engaged in this business which, over a year ago, hired home economists to study and improve the firm's situation. Various foods not commonly offered workers under the concessionaire arrangement have been tried out experimentally and records kept of their acceptability. It appears evident that some at least of the foods believed to be of high nutritive value, and which therefore nutritionists frequently recommend, have in fact a low acceptability as such, and can probably be used to a considerable extent only when worked into recipes of one kind or another; further developments in this field will be awaited with interest. It is certainly a hopeful sign that important units in the food concessionaire business have become aroused to the possibilities for improving their contribution to the feeding of workers.

THE DISPENSING MACHINE

In some plants foods and drinks are made available through dispensing machines, as well as through canteen carts wheeled through the establishment. This situation presents a twofold problem, one concerning the choice of prod-

ucts to be dispensed, the other involving education of the worker in making his choices. The nutritional advantage of offering milk as compared with soft drinks is obvious. In this connection it is only fair to point out that fluid—water—is needed by the body just as much as solid nutriment; and when the need to be met is that for water, milk is not a very satisfactory substitute. Taken as a recognized valuable part of the day's dietary, however, milk is an item for which there is no good substitute.

All of these items, then, have their proper place in the total picture, but too often that place has been enlarged beyond anything that sound nutritional practice can countenance. Experience can be cited in support of the view that most workers, when given the chance over a reasonable trial period, will increase their milk consumption and correspondingly decrease that of soft drinks. Such a result represents of course the effect of educational effort coupled with easy access to the more desirable product.

Another interesting development to be recorded in this connection illustrates how every branch of the food industry has become aware of the part it plays in the total nutrition picture, and the importance, therefore, of making that part a commendable one. Many confections can be dispensed by the machines located in industrial plants. The confectionery industry has been taking active steps to improve the nutritive value of its products, and is now supporting active research in this direction. The desire of the armed forces for various kinds of improved confections has doubtless had something to do in encouraging this.

A survey of our national food resources shows that there are many valuable foods which the American people could use, if they would; good examples are skimmed milk powder,

dried yeast, soybean flour, peanut flour, cottonseed flour, etc. Most of these products probably find their best use as ingredients of foods made according to a recipe. Some commercial products of high nutritive value have already been made from them, and these could of course be used in the lunch-box, or by the concessionaire, or even, in some cases, in dispensing machines present in industrial plants. Owners of such machines now have ample material of high nutritive value to choose from in stocking their machines, and as far as possible should base their choices on known nutritive values of the products.

The science of nutrition has developed to the point where it is quite proper to ask any purveyor of food just how good his product really is, and to expect an answer backed up, if necessary, by actual tests of some kind if the product is not a well known natural food or a mixture of such natural foods.

FEEDING OF SUPPLEMENTARY VITAMINS

The ready availability of various vitamins in pure form has led many industrial concerns to adopt the practice of giving these dietary factors to their employees. The wisdom of this practice, particularly if it involves an indiscriminate use, can certainly be challenged, and has been. One school of thought argues that it has been shown that a large part of the American people do not get sufficient vitamins to support optimal health; that workers in industry constitute a large part of the American population and presumably, therefore, belongs to this group; that this subnormal health is reflected in poorer industrial performance, earlier fatigue, poorer recovery from fatigue, and greater absenteeism; that administration of the vitamin does no harm, any excess not needed by the body being readily eliminated; the vita-

mins are relatively inexpensive; therefore, it is argued, the administration of vitamins by management to the workers constitutes a valuable contribution of that management to the health of these workers. Against this view can be cited the following line of argument: vitamins constitute only a part of the many dietary factors needed for health (it will be remembered that previously approximately forty individual items were mentioned as being needed for adequate nutrition); a diet of properly chosen natural foods furnishes not only the needed vitamins but other factors as well; therefore, if any dietary factors are needed by the workers, they should be furnished in the form of available natural foods of high nutritive value. To industrialists this means, of course, that the plant should furnish adequate eating facilities, something that is more difficult to do than to give out vitamin concentrates, pills, or capsules. It is doubtless natural, therefore, that many plants should have chosen to give vitamins instead of natural foods.

SPECIAL INDUSTRIAL HAZARDS

Another aspect of the matter deserves comment. There is evidence¹⁰ that workers handling certain chemicals are exposed to industrial hazards against which particular dietary factors may be protective. Foulgar¹⁰ cites trinitrotoluene—TNT—as an example of a toxic chemical against which a high intake of ascorbic acid—vitamin C—seems to be of considerable value. There have been reports that the effects of glaring light on vision can be counteracted in considerable measure by the administration of vitamin A; this vitamin has also figured in many discussions as a possible anti-cold agent, and this claim has been vigorously challenged. The value of a liberal supply of B complex vitamins in combating fatigue, and recovery from fatigue appears to

be subject to some debate. These illustrations emphasize to us the need for due appreciation of the *special industrial situation* for which one or more vitamins may be of great importance; and if the data from carefully controlled studies in this field prove a relationship of this type, obviously the dietary factor of interest should be provided, whether it be a vitamin, table salt, calcium, or some other substance. Such an attitude on the part of students of industrial hygiene means merely that there should be a sensible application of the results of good research.

NUTRITION AS A CHALLENGE TO PUBLIC HEALTH

Public health workers can do much to assist in the proper application of the newer knowledge of nutrition to industrial hygiene. They can advise and guide industrial managers and workers' organizations in relation to special situations. They can assist in determining whether the best practices are being followed in the operation of the feeding facilities in the plant; whether these facilities are under competent nutritional supervision; and whether the selections of foods to be offered are the best that can be made in the prevailing circumstances.

The problem of public education in these matters is always with us, and public health workers will of course do their part in organizing local nutrition classes, and either teach those classes or help to find and train others

for this work. There are many gaps in our knowledge in this field that must be filled. More studies of various types need to be carried out in industry. Public health workers who should find themselves facing an opportunity to encourage and participate in such investigations, in my opinion, should feel favored indeed; until these many studies have been prosecuted to a successful conclusion, we shall not have explored to the full the many possibilities for human welfare that reside in genuine knowledge of nutrition as a factor important for industrial hygiene.

Chest X-Ray Survey Methods in Practice

LIEUT. A. B. ROBINS, MC-V(S), USNR

United States Navy Yard, New York, N. Y.

CHEST x-ray examination of apparently healthy individuals has become an accepted method of tuberculosis case finding. It has been adopted by tuberculosis control agencies throughout this country; it is being employed routinely by the Army and Navy for all members of the armed services, and by the U. S. Public Health Service for workers in war industries. The British Government has recently announced its plans for the chest x-raying of all inhabitants of England. The procedure has even earned the distinction of having a feature article devoted to it in a recent issue of one of the country's leading weekly popular journals.

Three basic chest x-ray survey methods have been developed, the rapid roll paper method, roentgen-photography on 4 x 5 inch film, and roentgen-photography on 35 mm. film. Considerable controversy has arisen concerning the respective merits of these technics. Much of this controversy has been due to lack of familiarity of the participants with the methods in actual survey practice. Studies of the diagnostic accuracy of the three media have been carried out under circumstances bearing little relationship to field conditions of operation in either taking or reading of films. Observers have drawn broad conclusions based on the comparison of a few test or demonstration films. In general, important technical factors in the taking and handling of the

x-rays have been left out of consideration in the discussions. The effect of these academic comparisons and generalizations has been to produce a distorted picture of the problem of chest x-ray surveys and to prejudice the reader against one method or another. The subject is far too vital to warrant conclusions founded on such inadequate premises.

The opinions presented in this paper are based on 6 years' experience with two of the three survey methods. From 1937 to 1942 the author was associated with the Bureau of Tuberculosis of the Department of Health of New York City. During this period this agency x-rayed more than 350,000 individuals, using the rapid roll paper method on a contract basis. The work included all phases of survey operation from the planning of space to the reading and filing of films. Since April, 1943, the writer has been connected with a tuberculosis control program among industrial workers in a large shore establishment of the United States Navy. This program, carried out under the supervision of the Senior Medical Officer of the New York Navy Yard, Captain J. W. Troxell (MC) USN., and Comdr. T. R. Meyer (MC) USNR., Industrial Hygiene and Sanitation Officer, has included the taking of chest fluorograms of over 15,000 persons in less than 6 months' time. The 35 mm. roentgen-photographic method, provided by private contract, has been employed.

The work has called for reading of the films, follow-up on cases, and arrangement for the storage and filing of records and films. These two experiences have made it possible to compare the roll paper and 35 mm. roentgen-photographic methods in actual operation in large scale chest x-ray survey practice and have prompted the preparation of this report.

Comparison between the methods can best be made in terms of certain basic factors:

DIAGNOSTIC ACCURACY

In considering the question of the diagnostic accuracy of the different media there has been a tendency to overlook the primary objective of chest x-ray surveys, to screen out cases requiring further examination from those presenting no abnormalities requiring such examination. Some observers have compared the methods on the basis of their accuracy in detecting all pathological conditions. This is extremely valuable from a scientific point of view, but has little applicability in practice where only clinically significant lesions are of importance. Another fallacy has been a tendency toward using survey films as an ultimate criterion. Only lesions of obvious character can be accurately appraised on survey films, and in each instance all methods are satisfactory. If activity is in question, and serial films are required for comparison, the best medium available, 14 x 17 inch celluloid film taken at high speed on powerful machines with small focal spot tubes, must be employed.

When used for screening purposes, survey methods should be judged by three criteria: frequency of retakes for technical reasons, percentage of lesions overread, and percentage of lesions missed. There is little to choose between paper and 35 mm. photo-roentgenographic films with regard to frequency

of technical retakes. It is very difficult to secure good reproduction of the chest of very heavy patients with either method and we believe that all survey technics should provide for the immediate use of full size celluloid film in such cases. Even if instances of this type are counted, technical retakes have rarely been necessary. The exact percentage of such retakes varies with the reader and survey, but has not exceeded 1 per cent with either medium, which we consider a reasonable figure.

In our experience the percentage of cases regarded as suspicious on the survey film and negative on the 14 x 17 inch celluloid film has been higher with roentgen-photography than paper x-rays. This is to be expected as the short tube film distance in the former technic tends to exaggerate normal markings. Much of this difficulty can be overcome by thorough familiarity with the medium. It has been noted that the percentage of lesions overread tends to fall sharply as one continues to use any type of x-ray, and consistency in interpretation is reached only after several thousand films have been reviewed. Our percentage of unconfirmed lesions has been less than 0.5 per cent with either medium.

The most important criterion, and the most difficult to appraise, is the frequency of missed lesions. Moderately advanced and far advanced tuberculosis can be detected by all survey methods; minimal lesions will occasionally be overlooked on any type of film and by any observer. Unfortunately, in practice the latter is only determined by the subsequent discovery of the case in other ways, and the vast majority of errors probably remain undetected. In the Navy Yard all cases of incapacitating illness are cleared through the medical department and breakdowns from tuberculosis are readily detected. In the past 6 months we have learned

of only one lesion missed on the initial survey x-ray, and feel justified in assuming that this is a rare occurrence. In our hands both paper and 35 mm. photo-roentgenography have proved sufficiently accurate media for routine survey work.

RAPIDITY OF MAKING EXPOSURES

This has not been a factor of importance with either method. Both are operated at the rate of 500 exposures per unit per day routinely, and this can be increased to 1,000 a day for short periods of time. Since it is

rarely possible to reach this number in practice, speed in making exposures is no problem with roll paper or 35 mm. roentgen-photography.

FACILITY IN PROCESSING FILMS

In our work both paper films and fluorograms were provided by private contract, and the company supplying the service was responsible for the processing which was done in its plant. Should it become desirable, however, to assume the complete operation of the survey, including the developing of the films, it can be done readily

FIGURE 1—Cabinet which holds over 60,000 films

with 35 mm. roentgen-photography by providing a small photographic dark room. This is not possible with paper film at the present time. When transportation of film is a problem, 35 mm. film can be sent by ordinary or air mail, which is a decisive advantage these days.

CONVENIENCE AND SPEED IN READING FILMS

Thirty-five mm. roentgen-photograms can be read much more conveniently than paper film. The rolls of 35 mm. film occupy little space and can be carried easily from place to place. They require no elaborate equipment or special lighting for viewing. A small reading device of low magnification of the type widely used in photography has proved entirely satisfactory for the purpose. The films can be examined in any place where an electric outlet is available, and the work can be adapted readily to the convenience of the reader. With paper film an elaborate viewer with special illumination is required, and the reading can only be done at more or less fixed locations?

Thirty-five mm. film can also be read more rapidly. We have routinely reviewed 400-500 films per hour, including the time allotted for short rest periods. On rare occasions as many as 1,000 films per hour have been read. The normal reading speed with paper films is 200-300 films per hour, with a maximum of 500 films per hour. No greater eye strain has been encountered working with the small films than the full size films at these speeds. There are two principal reasons for the greater speed in reading small films. The more important one is the time saved in changing and turning rolls in the course of reading. A less important reason is the small size of the image on 35 mm. film, all of which can be encompassed by the eye at one glance. With larger films differ-

ent portions of the chest must be looked at separately, which is more time consuming.

EASE OF FILING FILMS

Roll film can be filed in rolls or individually. In most instances the former method is used. Rolls of 35 mm. film can be kept in a compact filing cabinet so as to be readily available at all times. Such a cabinet, designed and built at the New York Navy Yard, has been described in a recent publication.¹ Two views of this cabinet, which holds over 60,000 films in a space 54 inches x 36 inches x 11 inches, are shown in Figures 1 and 2. No such convenient method for filing paper film is available. In fact, the accumulation of rolls of paper film in large scale survey work presents so great a filing and storage problem that photography of paper x-rays on 35 mm. film has been resorted to. Thirty-five mm. films can also be filed individually with the case record, and in some instances the case record has been so designed as to provide a place for the attachment of the film. The only circumstances under which paper film can be filed more readily is with full size celluloid film. This is necessary in only a relatively small percentage of survey cases.

The above observations apply only to the roll paper method and roentgen-photography with 35 mm. film as used in our work. Other equipment, or the same equipment used under other conditions, may lead to quite different findings. Changes in chest x-ray survey apparatus and technic are occurring so rapidly that such differences are to be anticipated. A new type of cassette for paper film, which makes it possible to utilize existing dark room facilities, is now being tried out. Photo-electric control of exposure factors for roentgen-photography has recently been described. Rotating anode tubes are being tried out for taking survey films. Im-

provements in optical systems, screens, types of film, and developing solutions are the subjects of constant research. These, however, are developments for the future. The comparisons drawn in this paper are based on the methods of today.

Nothing has been said in this presentation concerning 4 x 5 inch roentgen-photography as we have had no

experience with this survey method. Numerous reports can be found in the literature concerning its diagnostic accuracy and there appears to be no reason to doubt its acceptability as a screening medium. It does suffer, however, from the drawbacks inevitable in any procedure in which films and cassettes are handled individually. The degree to which this impairs its effi-

FIGURE 2—Section of interior of cabinet

ciency can be appreciated from consideration of the factors mentioned in the previous discussion.

SUMMARY

Experience with the rapid roll paper method and roentgen-photography on 35 mm. film has demonstrated both to be satisfactory chest x-ray survey methods. Both possess a sufficiently high level of diagnostic accuracy for screening purposes. Thirty-five mm. roentgen-photography is the more flexible method, lending itself to the operation on either service or self-operated basis. Its greatest advantage, however, lies in the increased speed in

reading and greater convenience in handling of small sized films in roll form. This principle we believe is essential to practical survey operation, and will be a fundamental part of the survey methods of tomorrow.

ACKNOWLEDGMENT—The author wishes to acknowledge his indebtedness to Captain J. W. Troxell, (MC) USN, Senior Medical Officer of the New York Navy Yard, and Comdr. T. R. Meyer, (MC) USNR, Industrial Hygiene and Sanitation Officer of the New York Navy Yard for their interest and encouragement in this work.

Gonococcus Cultures—A State Laboratory Service*

MARGARET W. HIGGINBOTHAM, Sc.D., F.A.P.H.A.

*Bacteriologist, Division of Preventable Diseases, State Department of Health,
Minneapolis, Minn.*

SPECIMENS transported by express, bus, or parcel post, for gonococcus culture have been received and examined in these laboratories during the past four years. The procedure and results obtained during the first year have been reported.¹ Owing to the superiority of the results of cultures of shipped specimens compared to those of the microscopic examination of smears on glass slides, further attempts were made to find a satisfactory medium for shipping.

MATERIALS AND METHODS

Specimens—The specimens were obtained from patients attending outpatient clinics for diagnosis and treatment of gonorrhea and from patients referred to their private physicians for examination after having been reported as a source of infection. Cultures were made of all specimens received regardless of treatment being administered to the patients.

Media for shipping—Preliminary experiments using plates and slants of chocolate agar in addition to fluid media were made. Four sterile solutions were used during this study: (a) 0.2 per cent KNO₃ in distilled water, (b) distilled water, (c) horse blood-gentian violet (Cox), (d) ascitic fluid hormone broth. An approximate comparison

was made by inoculating two different solutions with each specimen on collection.

Shipping—One gallon hot-cold picnic jugs (Figure 1) were found to be serviceable and convenient for shipping specimens on ice. The material for culture, collected on sterile swabs, was emulsified in 1 to 2 ml. of fluid in 5 ml. vials. At this time two plates of solid medium (McLeod chocolate agar and cystine chocolate agar) were inoculated and a smear was made on a glass slide for microscopic examination. The plates were incubated within 4 hours and were the "control" cultures.

The inoculated vials of fluid were placed in a tin container which was then packed in ice in the jug and shipped to the laboratory. As many as eight specimens were packed in one jug.

Temperature and time during shipping—Preliminary experiments with gonococcal pus were made. Specimens in liquid suspensions were shipped at air temperature, refrigerated at approximately 10° C., and frozen with dry ice. Dry ice was not available in many towns and hence only a few specimens were submitted by this method. Dry ice was better than air temperature in the small series studied. Refrigeration at 10° C. gave better results than air temperature and was used for the routine cultures reported in this study.

In Minnesota specimens are usually delivered to these laboratories 18 to 24 hours after collection. This report of

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 13, 1943.

FIGURE 1—Outfit for shipping specimens for gonococcus culture and smear examinations: 2 vials of fluid, tin container for vials, jug, smear outfit which is placed in cotton bag tied to handle of jug.

culture studies is based on a 20 to 26 hour interval.

In making a comparative study of media it is realized that the technic of inoculation should be carefully controlled. However, in routine collection of specimens in various clinics and by different physicians this is not practicable. The results tabulated are from specimens collected routinely and are considered representative of those received in a state laboratory.

Solid media for laboratory use—On receipt in the laboratory each vial of emulsified specimen was plated in duplicate on McLeod chocolate agar and cystine McLeod chocolate agar. Other media were used in addition at times, i.e., Peizer,² Nile blue A-egg white, Gardner,³ Casamino starch agar, Mueller.⁴ All solid medium plates were incubated in 10 per cent CO₂ for 48 hours at 37° C.

RESULTS

The results of examination of "immediate" cultures, cultures of shipped

specimens and smears are given in Table 1. On *immediate culture* 170 specimens gave positive results and 1,223 were negative. Of the 170 specimens positive on immediate culture 80 or 47 per cent gave positive results after shipment; that is, the results of "immediate" cultures were superior to the shipped specimens by 53 per cent.

Comparing the immediate positive cultures and smears (Table 1) it is noted that the cultures gave 170 positive results compared to 54 given by the smears, that is, there were more than three times as many positive cultures as positive smears. The cultures missed three which were positive on smear examination and the smears missed 119 which were positive on culture. Both cultures and smears gave positive results in 51 specimens.

In the group of *shipped specimen* cultures there were 80 positive cultures against 54 positive smears. The cultures missed 25 specimens which were positive with smears and the smears missed 51 specimens which gave posi-

- = Specimens from which gonococcus colonies were not isolated

and laboratory findings in certain of the groups may be made. Of the 51 specimens which gave positive culture results on shipment and negative smear findings (Tables 1 and 2) 11 were from persons reported as sources of infection, 25 were from treated patients for release, and the remainder (15) were from persons clinically suspected of gonorrheal infection.

In Table 1 the parenthetical figures (16) and (52) show the number of specimens negative on smear examination which gave positive results on immediate culture and negative on shipped specimens, a total of 68. Of these 68 specimens, 12 were from persons reported as sources of infection, 36 were from treated patients for release, and 20 were from patients with clinical symptoms suggestive of gonorrhea.

In addition there were 10 positive cultures of shipped specimens (no immediate cultures available) which were not included in the tables. Six of these were from persons reported as

KNO₃ solution appeared to be better than water and water more satisfactory than ascitic-fluid broth for transmission. Possibly the lot of gentian violet used in the horse blood-gentian violet medium contained impurities which were absent in the preparation used by Cox.

SUMMARY

The results of this study indicate that the cultures of shipped specimens are superior to microscopic examination of smears alone for obtaining laboratory evidence of gonococcus infection, where facilities for immediate cultures are not available. Although the shipped specimen cultures were a little less than half as satisfactory as immediate cultures, the former were definitely superior to the smear examinations. The examination of cultures of shipped specimens together with smears yielded almost twice as many positives as smear examinations alone. The use of a simply prepared and inexpensive medium which

will keep on storage at room temperature at clinics and in physicians' offices is practical for routine use.

Dr. Trask Honored in Naming of a Liberty Ship

The late James D. Trask, M.D., of Yale University, was posthumously honored in May when a Liberty ship named in his honor was launched at the Bethlehem-Fairfield Shipyards in Baltimore, Md. Dr. Trask, who died in Chicago on May 24, 1942, while working for an Army Medical Commission under an appointment as consultant to the Secretary of War, was internationally known for his work in infantile paralysis.

This salute to Dr. Trask and his colleagues who are still carrying on polio research work was suggested by the National Foundation for Infantile

Paralysis and the ship is expected to be christened by his widow with prominent scientists from Yale University and Johns Hopkins University present at the launching ceremony.

Dr. Trask and his associate, Dr. John R. Paul of Yale University, received the first grant of the Committee on Virus Research made by the National Foundation after it was organized in 1938. The doctors published many papers on the disease and were honored a month before Dr. Trask's death by the award of the John Phillips Memorial Medal at a meeting of the American College of Physicians.

Block Organization for Health Education*

HOWARD Y. McCLUSKY, PH.D.

University of Michigan, Ann Arbor, Mich.

THE face to face talk of friend with respected friend is still the most effective means of passing on ideas and information. The radio is potent, but large numbers of people do not own radios, and if they do, one cannot be sure that they listen to the right programs. The newspaper is influential, but many people do not read it, and if they do, they may not read the right sections. But the exchange of talk is universal—in the pool hall, at the farmers' market, at the club, around the pot-bellied stove, in the transcontinental train, at the corner drugstore, or over the back fence, people pour out their ideas. If the talk were directed to one central topic, if the facts on which the talk is based were carefully verified, and if arrangements were made for such talk to go on in every home in the land, you would get a coverage and have a vehicle for public education unparalleled and unexcelled. The OCD Block Plan is a long step toward this objective.

Total war requires the participation of the total population. It is not surprising that soon after the outbreak of hostilities, many communities developed a method for bringing every family into home front war campaigns. This method sprang up spontaneously, independently, and at about the same time in different parts of the country.

The basic idea of the method was that one person in each block would be the key distributor of information about war programs. The idea was therefore known as the "Block Plan." This device proved to be so effective that the national Office of Civilian Defense in Washington recommended its adoption throughout the country. As a matter of record and as proof of the grass roots quality of the movement, it is significant that the block plan started *first* on the local initiative of local defense councils, and it was only after a considerable ground swell of operation and interest that the headquarters of the federal OCD adopted it as a part of national policy.

"Thus the Block Plan is simply a method of carrying out home front programs through a block by block organization of neighbors. It is a plan where neighbors can team together for war service with the help of fellow neighbors as their block leaders."

Under this scheme a community is divided into units of a small number of adjoining families. While the number of families in each unit varies in different communities, in general there are from ten to twenty families in each unit. "Each unit, regardless of size, is referred to as a block and may occupy: (a) an entire square city block, (b) a fraction of a square block, (c) one or both sides of a street, (d) an entire apartment building, (e) a fraction of a large apartment building, or (f) a country neighborhood.

Each unit or "block of families"

* Presented before the Public Health Education Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 12, 1943.

is headed by *one of its own number*. This is a basic feature of the plan and, with such a healthy, democratic quality, helps insure the plan against domination by any one faction, party, or interest. In the early stages of organization, the leaders are usually appointed from a panel of volunteers by some representative of the local defense council, but after the plan gets under way, the appointment of the initial leader is either confirmed by an election of the block group or he withdraws and a new leader is elected to fill the vacancy. All the block leaders are under the direction of sector or zone leaders, who in turn are united under a representative of the Civilian War Services Branch of the local defense council with some title such as chairman of the block plan or chief of the block leader service. Some variation of this plan operates in all types of urban and rural communities in all sections of the country. The term "block" is used to describe the working unit in communities of over 2,500 population, while the term "neighborhood" is applied to working units in communities under 2,500 population. The basic purpose is twofold, first, as already indicated, to secure universal participation of the home front in war programs, and second, equally important but less often utilized, to bring the opinions and suggestions of the rank and file citizen to the attention of civilian defense authorities for the better prosecution of the war. The plan is used for a variety of different programs.

Once the essential machinery of the defense council and block plan is set up, the effectiveness of the block plan depends largely on the *quality* and *training* of the zone, sector, and block or neighborhood leaders. Experience shows that the work of the leader is greatly facilitated if the program has been carefully explained via newspaper

and radio. Thorough use of these media identifies the block leader with the program he is attempting to explain, and enables him to concentrate upon getting action and the task of interpreting the program to the family unit. The essence of the educational process is twofold, first instructing the leaders in the program concerned, and second, transmitting the understanding they have thus developed to the families in their "blocks."

The application of the block plan to the field of health education can be made best with a series of illustrations. In Fenton, Mich., war clubs (Block Plan) on their own initiative undertook a program of education designed to bring about a general acceptance of the engagement of a public health nurse. A series of talks and demonstrations were given. These efforts led to a broad interest in public health beyond the original problem of securing the services of a public health nurse. In Fayetteville, N. C., block workers campaigned to encourage inoculations against typhoid, diphtheria, and smallpox. In La Junta, Colo., block workers were used to help check a diphtheria epidemic. The local director writes that, "The block leaders told the families on whom they called about the threat of diphtheria, warning the mothers to have their children immunized, advising them to keep their children with sore throats home from school, and asking if their children would submit to throat cultures." The director continues by saying that they "located 38 carriers of diphtheria and many were quarantined. They checked the spread of diphtheria temporarily at least, which with a shortage of doctors was very important."

In Mount Vernon, Ind., block leaders conducted a campaign to acquaint housewives with the importance of safety in the home, and to enlist them in the Indiana Home Safety Campaign.

In Richmond, Va., block leaders promoted health in their neighborhoods during the month of April, 1943, by forming Health for Victory Clubs, emphasizing the value of nutrition and home nursing, and stressing the advantages of an early diagnosis of tuberculosis. The Richmond block organization also originated campaigns to rid the city of rats. One feature of this effort was a drive to clean up the streets, yards, and alleys, and to beautify the city, as well as to starve the rats into an appetite for poison. Through the neighborhood leaders, Waldo County, Me., increased by 24 per cent the local use of enriched flour and bread in preference to plain white flour and bread. An excellent and effective program for making a survey in an attempt to stamp out infantile paralysis was made in Fort Worth, Tex., under the joint auspices of the Fort Worth and Tarrant County Health Departments, the Tarrant County Chapter of the National Foundation of Infantile Paralysis, and the Tarrant County Office of Civilian Defense. Another effective program for the elimination of rats, garbage disposal, and the control of the yellow fever mosquito was undertaken in New Orleans.

A very promising project of education for the prevention and control of venereal diseases was undertaken in one section of Wayne County, Mich. By adroit management, the coöperation of outstanding civic, religious, and municipal leaders was secured. Groups of block leaders received lectures and read pamphlets on the problem of venereal disease. After their instruction, leaders passed the information on to their neighbors. The coverage was not complete, but was more effective than anything heretofore attempted in that area.

Two more projects, in greater detail, will complete the material of this presentation. For the first, I quote part of

a letter dated July 2, 1943, written by Mrs. Allen C. Selmin, Executive Secretary of the Neighborhood War Clubs of Detroit, to Reginald Foster, who was then chief of the War Services Branch, OCD, Washington, D. C.

"History of the Project: About a half million persons have moved into Detroit in the last year and a half. The local Board of Health was anxious to continue their fine record, despite the fact that they had lost many nurses to armed services and private agencies. They therefore requested Neighborhood War Clubs to do the survey which their own nurses had been accustomed to do; a survey which would determine the danger spots in the city. They were particularly interested in knowing what families had arranged for immunization against smallpox and diphtheria.

"The Project: The Board of Health prepared the enclosed forms: the pink form to be filled out on each family in the city, the yellow ones to serve as instruction to the block leader who was doing the interviewing. These were distributed by Neighborhood War Clubs to block leaders who called on all the families in residence in a square block for which they were responsible. The forms were then returned to this office, coded, and when ten to twenty had been received from a block, were sent on to the Board of Health. That agency then made up the statistical reports.

"Results of the Project: At the present writing, about 50,000 of these reports have been sent to the Board of Health and, according to the annual report from that organization, have served the purpose for which they were intended. The results were limited by the fact that the block organization in Detroit was not complete. We are still sending these forms to block leaders as new blocks are organized in the city, and the Health Survey becomes the first project of a new leader. Block leaders find householders interested in

health problems. They are concerned about the dangers to their children who go to school with the children of families recently moved to Detroit.

"As a result of this service given to the Board of Health by Neighborhood War Clubs, we have recently been asked by them to take on a new project. The highest incidence of tuberculosis in Detroit is in the downtown, or transient, area. This falls within three of the four zones in Area 10. Our zone, sector, and block leaders are now making appointments for residents of these zones to have x-rays taken. Block leaders are attempting to do an educational job in this part of the community. This is being done under the supervision of a staff member of the Board of Health, who has been loaned to Neighborhood War Clubs for this job and for a health education job throughout the community."

For my last example, I will take a page from some pre-war experience which I had in one of the rural counties served by the W. K. Kellogg Foundation in southern Michigan. While the block plan was not in existence at that time, the Branch County Community Corporation was in the fields of health and child welfare roughly equivalent to a county defense council. I quote from the February, 1939, University of Michigan School of Education *Bulletin*:

"During the summer of 1938, the Branch County Health Department was in need of certain important data with regard to the health of the children in the county. The chairman of the Branch County Community Corporation was approached for aid in securing these data, and he presented the problem to the corporation. One delegate from each of the one hundred and five school districts was then appointed to membership in a seminar on county health problems. For several meetings over a period of two weeks this seminar gathered to participate in a discussion

led by the members of the staff of the county health department, dealing with the physical welfare of the children in the county. In the course of these discussions, an interview schedule was described and the members of the seminar were instructed in its use. Each delegate applied the schedule to every family in his respective school district. These data were turned in to the office of the county health department for tabulation. This is probably the first time a complete inventory of the physical welfare of children has ever been secured in any area as large as Branch County. It was accomplished without any cost to the county. The process of adult health education for the one hundred and five delegates securing the data and for the families they interviewed was very effective."

In conclusion, I want to stress one basic and inescapable fact. All programs designed to enrich the lives of people and communities suffer from a universal plague. They reach and affect only a paltry fraction of the public for whom they are intended. Many of us talk to other professionals about what should be done with the great unwashed. Others reach a few laymen who in general are the least needy of the population. We rarely touch the man who needs it most, and if we do, for everyone we reach, there are thousands who never hear our story.

The OCD Block Plan is the most effective cure for this plague that I know. Nothing approaches it in coverage and the possibility of universal education under grass roots leadership. If I were a professional in public health education in the United States, I would do everything in my power to build up the OCD Block Plan in my community and to see that it is used for a problem that is vital in war and in peace, namely, the protection and development of the health and fitness of the general public.

Preparing High School Students for Community Service^{*}

GRAHAM L. DAVIS

Hospital Director, W. K. Kellogg Foundation, Battle Creek, Mich.

THE long-range objectives of the community health service course for the high school girl in Michigan are:

1. Broaden her vision and develop an awareness of community health problems and resources for solving them.
2. Develop an understanding of her responsibility for safeguarding and improving individual, family, and community health.
3. Develop competence in procedures and skills for dealing with illnesses, emergencies and similar health problems.
4. Develop an interest in and appreciation of selected health professions, such as nursing, medicine, public health, dentistry, laboratory work, and nutrition.

Two incidental and more immediate objectives, directly related to the war, are:

1. To provide overcrowded and understaffed hospitals and other health agencies with sorely needed assistance.
2. To recruit student nurses for the United States Cadet Nurse Corps.

The pressing nature of these immediate objectives focuses attention strongly upon the ineffectiveness of the theoretical and practical training for healthful living and care of the sick in the average school. These are sadly neglected subjects as compared with their importance in the life of the individual. The millions of young men and women, rejected by the armed forces and the war industries because of physical or

mental defect or disability, testify to that fact. These young people must feel bitter toward a supposedly enlightened nation that failed to teach them and their parents how to prevent the great bulk of these disabling illnesses and injuries. Physical and mental fitness is a dominant factor in winning the war. The survival of a nation and its influence in the post-war world will depend largely upon the health and vigor of the individuals who make up its population. The high school girl, the future mother of the race, is in a strategic position to do more to improve health conditions than any other person.

More emphasis has been placed in the school curriculum upon healthful living and care of the sick in the W. K. Kellogg Foundation's seven-county Michigan Community Health Project than in most places, but it took a war and the acute shortage of nurses in the coöperating hospitals to force the issue. Nurses deserted the hospitals to join the armed forces or to follow their husbands to training camps. Older women in these smaller communities with leisure time to become Red Cross nurse aides are relatively few in number. The armed forces and the high wages paid unskilled workers in war industries attracted the younger women. That left the high school girl as the only important source of woman power to fill the gap, and it was discovered that she was ready, willing, and anxious

^{*} Presented before the Public Health Education Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 12, 1943.

to do her part. She had an uneasy feeling that she was not making her full contribution to the war effort. Her high school brother was in the Victory Corps and her older brothers and sisters were in the armed forces or war industries.

When some 40 girls in the Lakeview School, located in a suburb of Battle Creek, who had discussed the subject in class with their teacher, petitioned the school authorities to give them training that would fit them for voluntary service in the overcrowded and understaffed local hospitals, officials of the Foundation were consulted. They enthusiastically approved the project, not only as a war measure but as a permanent part of the high school curriculum. That was one year ago.

When the superintendent of public instruction approved the project, he asked the Foundation for sufficient funds to try it out in 20 high schools during the second semester. The number was increased to 26 when 80 high schools asked to be included. The home economics teacher at the Lakeview School and the teacher of health subjects in the Ann Arbor schools, who is a registered nurse, sacrificed their Christmas vacations to outline the course. Two of the schools decided to make it compulsory for all senior girls and the other 24 offered it as an elective. Approximately 1,000 girls were enrolled.

The directing committee was composed of representatives from the Departments of Public Instruction and Health and the State Board of Control for Vocational Education. A committee of experts evaluated and revised the course content this past summer on the basis of experience.

The planning group is usually composed of the school administrator, the teacher, the nurse consultant, the hospital administrator or administrators, if there is more than one hospital in

the community, and the health officer. They inventory the local health agencies, such as the health department, hospital or hospitals, maternity, well-baby, immunization and other clinics, Red Cross, tuberculosis association, family welfare agency, school health service, municipal sewage disposal plant and water works, physicians, dentists, and visiting nurse association, and they map out the teaching program so far as these agencies are concerned.

A suitable classroom instructor, usually the home economics teacher, teaches the course with the assistance of a nurse consultant. The nurse supervises the training and practical experience of the students in the hospital, health department, or other health agency and assists the classroom teacher with the theoretical instruction. The usual classroom period is one hour a day with an additional hour of practical experience.

Unit I includes a survey of local health agencies and personnel and an appraisal of their adequacy to serve the community effectively.

Unit II is an analysis of the health status of the student and includes a complete physical examination. This is planned as a learning experience and is required before the student goes to the hospital for practical experience. One class discovered from the chest x-rays that one-third of its number had previous tuberculosis infection. This led to a case finding program in the whole school. Another class discovered how few students had been immunized against the preventable contagious diseases. They conducted a campaign to have all students immunized.

Unit III has to do with family health, with particular reference to the mother and infant, and includes control of communicable diseases, home nursing, family relationships, and sex education.

In Unit IV, community health, the activities of the local health agencies, including the health department, come

in for more detailed study. It includes school health, the environmental factors affecting health, and mental health of the adolescent.

In Unit V the girl learns about nursing skills.

Unit VI is a study and analysis of the health professions, including nursing, medicine, dentistry, nutrition public health and the clinical laboratory, and the opportunities for service in these fields.

The course was offered in the senior year, but a few juniors were enrolled. The girls elected to take the course with mixed motives, as might be expected. Some had decided upon nursing as a career and, strange to relate, when they got a taste of it a few decided it was not what they wanted to do. This course should cut the 35 per cent mortality the first year in schools of nursing. Other girls, who had no predilection toward nursing, decided that was what they wanted to do. Still others took the course because they had completed all their required subjects and this elective appeared to be a snap. They were in for a shock, but they bore it nobly.¹

Some 300 of the 1,000 students enrolled indicated that they planned to enter schools of nursing. Others went to work as regular hospital employees, and a few are taking up medicine, dentistry, clinical laboratory work, and dietetics. The suggestion that high school boys should also be enrolled in the course is also being given careful consideration.

The girls usually become very impatient to get into the hospitals and other health agencies during the first two or three weeks, which are devoted entirely to classroom instruction. More instruction occurs in the hospital before they are allowed to put into practice what they had been taught in the classroom. Department heads lecture on the functioning and why and where-

fore of their particular departments. Then the girls are allowed to perform the tasks for which their preliminary training has fitted them, such as answering calls from patients, folding linen, repairing rubber gloves, cleaning up the room and making empty beds after patients have been discharged, running errands, and helping to prepare trays and feeding the patients. After they became more proficient they were given additional responsibilities in nursing the patients.

In the health departments they visit with the public health nurse and sanitary engineer. In one community they discovered sanitary conditions in a trailer camp were far short of ideal. When they appeared before the city fathers, the mess was promptly cleaned up. Food handling in restaurants and bakeries was bad in another community. They did something about that.

One student, on a prenatal visit with a public health nurse, confided to the nurse her own need and that of her friends for "sex education." A later classroom discussion resulted in a panel discussion before the student body on boy and girl relationships. A physician, nurse, minister, parent, teacher, and student were on the panel. This and later discussions caused the formation of a planning committee, composed of a representative from each high school grade, a teacher, from each of the elementary and secondary schools, and community leaders. This committee is working out a program to improve social relationships among boys and girls. An interested civic group plans to finance the services of a psychiatrist to aid in a continuing program.

Everyone connected with the project—teachers, nurses, hospital administrators, health officers—was most enthusiastic about its possibilities. Many of the girls put in extra hours working in the understaffed hospitals that were not required by the course. The assist-

ant principal of Highland Park School in Detroit writes:

We started out this course with three sections, the third . . . added by popular demand. The interest . . . increased during the semester. I have talked . . . with many of the girls . . . most enthusiastic about it . . . a definite contribution to the curriculum. . . . The wife of one of the leading doctors at Henry Ford Hospital thinks it is the finest course her daughter has ever taken. The daughter is an excellent student . . . preparing for Vassar College . . . significant evaluation by an intelligent person.

Comment by a hospital administrator:

The students are well informed in elementary nursing procedures, painstaking in their work, and, above all, eager to make themselves useful. Several of these girls have already developed vocational interest in nursing . . . while all of them think that the course has been conducive to better health, both for themselves and for their respective families.

The American Hospital Association has taken the bulletin,² published jointly by the Michigan Departments of Public Instruction and Health for use as a handbook by schools and health agencies, and sent it to all its 3,200 member hospitals with a recommendation that the hospitals get behind this on a nation-wide basis.³ It means much to hospitals now in the way of practical help with the care of patients and the recruiting of student nurses. It also enlarges their opportunities for community service and increases their prestige as centers of health education.

This school year (1943-1944) over 200 Michigan high schools will give the course. About 50 of the larger schools that graduate classes in February will offer it in both semesters. The plan is, after this year, for the Michigan Department of Health, through coöperation of its county health units, to take over responsibility for the nurse consultant and planned training of the students in the local health agencies. The idea is spreading to other state departments of health and public instruction and to Great Britain. Some twenty states are negotiating with the W. K. Kellogg Foundation for financial assistance in getting the course started.

This is primarily a health education venture in which the schools and health agencies coöperate to give high school girls training that is both theoretical and practical in healthful living and care of the sick. They and their progeny should make better soldiers and war workers in the next war. If that war does not happen, the nation, so far as Michigan is concerned, should be much better equipped mentally and physically to maintain its prestige and leadership in the post-war world, a practical application of the fruits of positive health.

THE U.S.P.H.S.

THIS has been an important year for the Public Health Service in two respects. The first of these is the reappointment for a new term of Surgeon General Parran. The earnest devotion and the administrative skill with which he has conducted his difficult task have made him an ideal public servant; and a leader whom the rest of us in the public health profession are proud to follow.

The second event of the year is the passage of the U. S. Public Health Service Reorganization Bill. This bill simplifies and coördinates the work of the Service under four main bureaus: the Office of the Surgeon General (including, among others, Divisions of Public Health Methods, of Dentistry, and of Sanitary Engineering); the National Institute of Health which remains the research arm of the Service; the Bureau of Medical Services (which includes Quarantine and Mental Hygiene); and the Bureau of State Services (which includes Venereal Diseases and Industrial Hygiene). Thus, final administrative authority is concentrated in four channels, rather than ten or twelve. The chiefs of the four bureaus and the heads of certain divisions acquire a rank comparable with that of Brigadier General in the Army which is a welcome acknowledgment of the importance of their work. Dentistry and engineering, in particular, occupy more important positions than before. It is perhaps unfortunate that public health nursing did not receive similar treatment. On the whole, however, the reorganization makes for efficiency and recognizes the prestige which the Service has so fully earned.

The Bulwinkle Bill (H.R. 4624), now before Congress, will clarify and codify all the laws relating to the Service; and should further strengthen the work of the organization.

TRAINING IN TROPICAL MEDICINE

ON the inception of a war which carried our armed forces into the tropics, it became an urgent necessity that the medical personnel of the Army and Navy should be trained to meet the problems of disease prevalent in those areas.

This has been accomplished with notable success by intensive courses in tropical medicine at the Army and Navy medical schools, by the publication of new textbooks and directives, and by the practical experience of medical personnel with the armed forces in tropical regions. The program of War-Time Graduate Medical Meetings at military hospitals in this country has also included lectures on tropical diseases.

Training has been extended into the medical schools by a program involving travelling lecturers, intramural courses and field experience for instructors, and the provision of teaching material. In this program the Army and Navy, the U. S. Public Health Service, the Office of the Coördinator of Inter-American Affairs, the National Research Council, Tulane University, the John and Mary R. Markle Foundation, the Rockefeller Foundation, the Commonwealth Fund, and the United Fruit Company have coöperated with the Association of American Medical Colleges. The American Foundation for Tropical Medicine, through the support of commercial firms, has made grants to a number of medical schools to encourage teaching and research. The primary purpose of this program is to furnish a background in tropical medicine to medical students who will soon become officers, in the Army and Navy.

In addition to training personnel for the active prosecution of the war, it is necessary to look forward to future needs. Although we have been assured that if proper precautions are taken there is little danger of the establishment of tropical diseases in this country on the return of our troops, the medical profession and public health agencies must be on the alert to diagnose and treat cases which occur, and to prevent their spread to the civilian population. The increase of air transportation which will continue after the war, and which will bring occasional cases of tropical diseases into the country, also emphasizes the importance of preparedness. Furthermore, American participation in the rehabilitation of occupied areas, and in the long range task of improving health conditions throughout the world in the post-war period, present a challenge calling for adequate training of the civilian medical profession and of public health personnel.

Some steps have already been taken to meet this need. The DeLamar Institute of Public Health at Columbia University has established a full-time Department of Tropical Medicine. Tulane, Columbia, and the University of California are giving short courses for physicians this spring. The American Society of Tropical Medicine has a committee which is planning an educational program for physicians. Many state and county medical societies are including tropical medicine in programs of their meetings. A few state and local health departments have promoted programs in malaria and other parasitic diseases, and have also taken steps to give more extended training in tropical medicine to epidemiologists and laboratory directors. In this training the Army Medical School, the U. S. Public Health Service, and the Association of American Medical Colleges have been and are willing to coöperate. Other state and local health departments would do well to develop such a program which might well be coördinated by the leadership of the U. S. Public Health Service. Not only will it prove profitable to discover and control possible factors in the transmission of tropical disease, but those participating in such training will be fascinated with the life cycles and identification of parasites and with the intricacies of their epidemiology. No field of medicine holds more interest for the student of disease prevention. It is a cause for satisfaction that we, in the United States, are at last making a concerted attack on the problem.

WHO KILLED COCK ROBIN?

THE reduction of the death rate by approximately 40 per cent during the first four decades of the present century is one of the most significant events in human history. In such an achievement, there is glory enough for all. Health officers, public-spirited private practitioners, engineers, nurses, laboratory investigators, social workers, educators have all participated in the task.

To claim the fruits of victory for one individual professional group is therefore unwarranted. To associate them with a particular sector of one profession operating on a particular economic plan is still more unjustifiable. Yet this is what has been attempted in the flood of propaganda literature issued by the publicity staff of the "National Physicians Committee for the Extension of Medical Service" and distributed on a vast scale through the medium of certain agencies in the drug trade. The committee states that it has printed 20 million copies of one of these leaflets, which claims that the achievements of the past years have been accomplished by "American Doctors" operating under "the American system"; and it is obvious that, by the American system, is meant the private practice by individual physicians on a fee-for-service basis—since the entire flood of this propaganda is directed against any further participation by government in the development of more adequate medical care. Such an argument obviously raises the question whether American doctors practising on the particular system which the National Committee prefers, or on the equally "American" plan of official public service, deserve a major share of credit for our reduced death rates. As Governor Smith used to say: "Let's look at the record." The pertinent points of this record are indicated in the following table:

CHANGES IN MORTALITY
1900-1940

	Death Rate per 100,000		Per cent Reduction	Actual Deaths 1940	Deaths Which Would Have Occurred in 1940 at 1900 Rates	Number of Lives Saved per Year
	1900	1940				
Typhoid and paratyphoid fevers	35.9	1.1	97	1,443	47,173	45,736
Diphtheria	43.3	1.1	97	1,457	56,896	55,439
Diarrhea and enteritis	133.2	10.3	92	13,573	175,025	161,452
Measles, scarlet fever, and whooping cough	34.8	3.2	91	4,300	45,727	41,427
Tuberculosis	201.2	45.9	77	60,428	264,377	203,949
Pneumonia and influenza	180.5	70.3	61	92,525	237,177	144,652
All other causes	1,126.1	944.5	16	1,243,543	1,479,695	236,152

In this table are shown the actual results accomplished between 1900 and 1940 in the reduction of mortality from the five causes of death with which the organized health forces of the community have been concerned, and also the corresponding reduction in pneumonia and influenza, where responsibility has been shared between the public health officer and the private physician. The last line of the table includes the changes in mortality from all other causes taken together. Many of these have also come within the scope of the public health program.

It will be noted that typhoid fever and diphtheria mortality rates have been reduced by 97 per cent. The results accomplished in the case of typhoid fever, have been due to the work of the engineer, to purification of the public water

supplies, improvement in sanitary conditions, and to epidemiological control and immunization programs, conducted by health officers. In the case of diphtheria, administrative control, and the use of antitoxin and later toxoid, are responsible for the accomplishment. The basic discoveries in these fields were made by men like W. H. Park working in public health laboratories, and introduced by health officers like Hermann M. Biggs, often in face of vigorous opposition from the practitioner.

Diarrhea and enteritis of infants has been reduced by 92 per cent through the pasteurization of milk supplies, under the leadership of public health authorities and through the establishment by boards of health and visiting nurse associations of well baby clinics for the instruction of mothers. Here again the initiative came primarily from the organized health forces representing the public interest.

The group of infectious diseases of childhood, measles, scarlet fever, and whooping cough, have shown a 91 per cent reduction in mortality, due in large part to vigorous and energetic epidemiological control on the part of public health authorities. Tuberculosis, which has been cut down by 77 per cent, represents the result of a program carried on in nearly all its phases through the leadership of public health departments, public health clinics, and publicly maintained sanatoria. Here, again, it should be recalled that the introduction of the first program for the reporting of tuberculosis was strenuously opposed by the medical profession.

In the case of pneumonia and influenza the practising physician deserves a lion's share of the credit. Even here, however, it should be pointed out that the basic discoveries in regard to serum treatment and the use of sulfa drugs were made by salaried physicians in the employ of public health laboratories and foundations and universities, rather than by private practitioners.

It seems certain that the organized public health profession rather than the private medical practitioner is responsible for a major part of the gains which have been made during the past forty years.

It is no doubt true that the "Other Causes" of death listed in the last line of the table are much more difficult to control than those which the public health administrator has so successfully attacked; but it may be hoped that a sound system of prepayment which will make good medical care available to the lower economic half of the population, now woefully lacking in such services, would produce notable results in the reduction of many other causes of death than those which have so far been successfully attacked.

BOOKS AND REPORTS

This Milk Business—A Study from 1895 to 1943—By *Arthur Guy Enock*. London: *H. K. Lewis & Co., Ltd.*, 1943. 243 pp. Price, \$4.75.

A realistic discussion is presented of the production, processing, and distribution of milk in England, drawn from the author's experience of more than 40 years as a consultant on dairy and refrigerating problems. A plea is made for increased milk consumption in England, better official regulation and control of sanitation, and a fair return to farmers without undue increase in retail price.

The importance of pasteurization is stressed. The use of the process of holding milk at 145° to 150° F. for at least ½ hour is urged as against high-temperature, short-time pasteurization at 162° F. for at least 15 seconds. The author claims that high-temperature pasteurization damages certain food properties of milk and that the holding time for installations in England is uncertain. For this reason and because milk pasteurized by both the low- and the high-temperature processes often is placed in unsterile bottles, the author urges in-bottle pasteurization as the ideal process. Good laboratory results are reported on samples of milk from large plants in England bottling milk at 145° to 146° F. and holding it for 30 minutes in air in an insulated holding chamber. Lower cost per gallon is claimed for the in-bottle process as compared with regenerative heating. Actual figures are not given as they are considered to be confidential.

Many problems discussed are somewhat similar to those confronting us in the United States. However, the author's views on such things as the bad effect of high temperatures for short

times on the food properties of milk, the need for an upper limit in the definition of pasteurization, the superiority of inspection over the testing of the milk itself, and the uncertainty of the holding time for high-temperature, short-time pasteurizers are not in accordance with experience here.

W. D. TIEDEMAN

Micromeritics — By *J. M. Dalla Valle, M.S., D.S.* New York: *Pitman*, 1943. 428 pp. Price, \$8.50.

This very interesting and comprehensive volume summarizes in a most exhaustive way the whole field of the technology of fine particles.

The volume deals with material in the fine state of subdivision from many points of view, covering the subject in 18 chapters, each one devoted to an important aspect of the problem. Many of these are not of direct interest to the public health worker; for example, chapters such as the Dynamics of Small Particles; the Electrical, Optical and Sonic Properties; Thermodynamics of Particles, Capillarity; Muds and Slurries; and the Theory of Fine Grinding.

Several of the chapters are of more direct interest to the public health worker, such as the chapters dealing with Methods of Particle-Size Measurement; Determination of Particle Surface; Transport of Particles; the Collection and Separation of Particulate Matter from Air; and Atmospheric and Industrial Dust, the latter, of course, being the chapter of most interest to the public health worker.

The volume is exhaustive in its treatment of the subject and in each case deals with basic formulae in a critical and comprehensive manner.

The chapter dealing with Atmospheric and Industrial Dust concerns itself with the dispersion of dust and smoke, atmospheric pollution, industrial dust, particle sizes of industrial dusts, methods of sampling and analysis, and finally closes with a brief but concise discussion of the subject of the control of industrial dust.

The volume is well printed, contains numerous references to the literature, and closes with a valuable bibliography of some 38 pages. There is an appendix containing useful constants and conversion factors of frequent occurrence in this field.

This book should be in the hands of everyone really interested in the field of the technology of fine particles and, so far as the public health worker is concerned, it should prove a useful reference volume.

LEONARD GREENBURG.

A Manual of Methods for Organizing and Maintaining a Central Tuberculosis Case Register—By *Edward X. Mikol, M.D.* New York: National Tuberculosis Association, 1943. 70 pp. Price, \$1.00.

Only one who himself has been through the experience of setting up a central tuberculosis case register can fully appreciate the advantage now available to all through the publication of this *Manual* by the National Tuberculosis Association. The author has a background of wide experience as a member of the staff of the Division of Tuberculosis of the New York State Department of Health and the *Manual* has been prepared in coöperation with the statistical service of the N.T.A.

The central case register is presented as a superior administrative device intended as an aid in the operation of the tuberculosis control program. Such a register should preferably be maintained by a county or city health department, or by a tuberculosis hospital. The

Manual declares that the decision to establish a case register is wise only when the local tuberculosis control program is and has been well organized under competent supervision. The author and the Association are to be congratulated on this publication.

REGINALD M. ATWATER

On the Influence of Trades, Professions, and Occupations in the United States, in the Production of Disease—By *Benjamin W. McCready, M.D., 1837.* Baltimore: The Johns Hopkins Press, 1943. (With an introductory essay by Genevieve Miller, M.A.) 129 pp. Price, \$1.75.

This book is Volume IV in the Fourth Series: Bibliotheca Medica Americana, representing the publications of the Institute of the History of Medicine, The Johns Hopkins University.

For those who are interested in or doing industrial hygiene, medicine, and health work, this book represents one of the most important volumes in the history of the development of industrial and occupational medicine in this country.

The original material was written as an essay in a contest sponsored by the Medical Society of the State of New York in 1835; for which the prize was \$50. Dr. McCready wrote the book at the age of 23 and had been graduated only two years before from the College of Physicians and Surgeons, and had served a term as house physician at the New York Hospital. The author was considerably influenced by the book published in England in 1831 by Dr. C. Turner Thackrah, whose book was the second all-inclusive monograph on occupational diseases, following Ramazzini's immortal work in 1700.

Included as chapter headings are those with reference to agriculture, laborers, housing, seamen, factory operatives, artisans, professional men, liter-

ary men, and general causes of poor health.

The essay represents a remarkably mature and realistic approach to the problem of occupational diseases as it occurred in the early 19th century in America. Remedial proposals are forecasts of the future when housing codes were established and when industrial establishments provided safety devices, proper ventilation, shorter working hours, recreational activities, and convenient sanitary facilities. Particularly foresighted was Dr. McCready with respect to health education for the masses, the principles of which are not yet extensively and generally applied in industrial groups.

The book deserves the most careful perusal and reflection of industrial physicians and others who should understand the economic and social background of American industry. The publishers are to be congratulated on an invaluable contribution to American industrial medical literature.

C. O. SAPPINGTON

Dona Eugenesia y Otros Personajes—Edited by Dr. Manuel Gonzalez Rivera, Professor of Health Education in the School of Health and Hygiene. Mexico: Talleres Tipograficos Modera, S. A., Comonfort 44, Mexico, D. F., 1943. 210 pp.

This readable little book in health education was compiled from the home work of physicians and nurses studying in Mexico's School of Health and Hygiene. Out of their personal experience as physicians and nurses, they wrote to good effect of disease and hygiene in stories, poems, radio dialogues, and brief texts that might be used as "spot" announcements of health services.

Dr. Manuel Gonzalez Rivera, who teaches health education and is also director of health education for Mexico, selected the items for this book from

the work of his pupils. He also contributed the opening story, "Dona Eugenesia," which tells how one girl learned that gonorrhea may wreck a marriage and what she did about the problem of gonorrhea in her own engagement. The other authors treat of venereal disease, tuberculosis, typhoid fever, malaria and other diseases, of their prevention and their cure. They stress the help that people may secure from clinics, from doctors, nurses, and sanitarians in getting well and staying well.

These writings have flavor as well as health information. Market sanitation, for example, is expounded in the poem "Don Candelario" by Dr. Fernando Fernandez Alfaro. "Un cuento de amor . . . y de limpieza" by Eva Villaneuva Vega is a folk story of personal hygiene.

Directors of health education and teachers will be interested in this adventure in health education. Teachers who wish to direct their pupils to the health problems of other countries will be glad to find it.

Dr. Gonzalez in introducing the book says that it was designed particularly to aid the doctors and nurses who work in the rural areas.

HAZEL O'HARA

Dental Facilities in Philadelphia—A Survey of Sixty Dental Clinics—Philadelphia: Health Division, Council of Social Agencies, 1943. 46 pp.

The foreword of this report opens with the statement that inquiries such as this "begin with the assumption of some kind of inadequacy." The inadequacy of dental care in American cities for those who must depend on clinics for such attention is a matter of record, but it is well nevertheless to have it brought home from time to time.

This report states that in Philadelphia 500,000 children of preschool and school age were in need of immediate

dental care, and that 70 per cent of these children received no reparative dental treatment whatever in the year the study was made. No estimate was given as to the situation for adults, but the inference is permissible that it was essentially the same.

The purpose of the study was to "assemble facts which would be used as guides in planning for the future a satisfactory . . . dental program." The study was planned to show resources for the dental care of the indigent and how these resources could be used to the best advantage. Agencies offering dental care were classified as to type (hospitals, non-hospitals, dental schools) and as to geographical distribution. The various agencies were then examined as to facilities, staffs, and services offered. Tables show clearly the situation under these headings for the various types of clinics. Exclusive of the dental schools it was estimated that 75,000 patients were served during 1942.

This study was entirely objective, no effort being made to develop pleas for more dental care for the population of Philadelphia or to stress the health value of regular dental care. For that reason the recommendations deal largely with things as they are—the best use of present facilities and man power, urging, however, increased funds to secure more paid dental personnel to put all present dental chair hours to work.

The report does, however, provide much factual material which can be used in campaigns to arouse public interest in dental health, especially for the child population. It is an excellent study of its type.

JOHN OPPIE MCCALL

Prepayment Medical Care Organizations—By Margaret C. Klem. *Social Security Board, Washington, D. C. (November, 1943.) Bureau Memo. No. 55. 252 pp.*

The Bureau of Research and Statistics of the Social Security Board has prepared this memorandum for the use of its staff and for limited circulation to other administrative and research personnel concerned with the subject of prepayment medical care. It contains brief, one page digests of the essential facts regarding about 250 prepayment plans.

REGINALD M. ATWATER

Medical Parasitology and Zoölogy—By Dr. Ralph Walty Nauss. *New York: Hoeber, 1944. 534 pp. Price, \$6.00.*

After long experience in the teaching of medical parasitology and zoölogy to students of the Cornell Medical College in a limited period of ten weekly sessions of 3 hours each the author has condensed the practical essentials of these broad subjects into a text of less than 400 pages, exclusive of Appendices and the Glossary.

Part One deals in seven chapters with pathogenic and commensal protozoa, including amebae, flagellates and sporozoa, with special chapters on amebiasis and malaria.

Part Two in three chapters has to do with parasitic helminths, with particular emphasis on those causing disease.

Part Three in four chapters deals with insects and their direct or indirect relation to disease transmission.

Part Four in three chapters treats of venomous reptiles, stinging insects and injurious aquatic forms of animal life.

There are nine Appendices covering 101 pages on technical methods essential to the study of animal parasites, including excellent descriptive classifications of venomous reptiles.

In the Glossary is an identification key of animal parasites and arthropods, which more logically belongs among the Appendices. The Glossary proper could well have been omitted, in that it contains only a fraction of the technical terminology employed in the book.

Likewise it contains too many simple terms, such as rectum, ovary, mucus, habitat, and fang, with which even high school students should be familiar.

The presentation of the subject matter is concise, factual, and current. There are 16 pages of excellent bibliography.

The book is unusually well illustrated with 95 figures and 15 tables. With few exceptions these have been borrowed from acceptable sources, and have been properly accredited.

Not only to the medical student, but also to the clinician and laboratory technician this book should be very useful for both instruction and ready reference.

T. F. SELLERS

The Education of Nurses—By Isabel Maitland Stewart. New York: Macmillan, 1943. 399 pp. Price, \$3.50.

This book is most timely and should prove a springboard and guide to the profession as well as an orientation for the ever-widening circle of people not in the profession whose work is increasingly concerned with nursing. In these trying times the profession needs all the perspective it can get and non-nurses need to have nursing interpreted to them. The book furnishes a basis for meeting both needs, as well as a challenge.

In the first six chapters, nursing is described concisely from its earliest beginnings in primitive society through the Christian era to the time of Florence Nightingale (1860) "when nursing came into its own as a separate secular profession"; through the transplanting of the Nightingale system in this country (1873-1893), the subsequent periods of professional self-government, legislation (1893-1913), studies of cost, administration, curriculum, and emergence of the collegiate type of school (1913-1933), and fundamental readjustments up to the present day (1933-

1943). The meat and the challenge are in the last two chapters, in which the author discusses with clarity and wisdom a dozen or so important problems, some old, some new. The most fundamental seems to the reviewer "the need for a reconstruction of our philosophy of nursing education to make it more consistent within itself and to bring it into harmony with accepted democratic principles and with modern methods of education." Efforts to solve our other problems will be conditioned by the extent to which we think through and reshape our philosophy.

Throughout, nursing education is discussed in relation to the social milieu of the times. One of the book's chief values lies in the careful portrayal of nursing education in relation to the forces which have impinged on it—the church, army, medicine, education, science, etc.—through relatively static societies to the rapidly changing order of today. Nursing in the total social setting and its stake in democracy are the unifying threads and "if we are to pursue a steady upward trend" our leaders must have such a concept. Miss Stewart offers real help which should enable us so to plan and act that "what is best for the community as a whole, not what nurses want for themselves, must be the prime consideration, though the rights of the professional group must be safeguarded."

MARY C. CONNOR

Childbirth Without Fear: The Principles and Practice of Natural Childbirth—By Grantly Dick Read. New York: Harper. 259 pp. Price, \$2.75.

In this book Dr. Read explains his theory that childbirth without physical complications should be painless because reproduction is a natural function for all living creatures and no physiological function in the body gives rise to pain under normal conditions.

He recounts his search for the cause of the pain usually associated with childbirth. He explains how fear disturbs the neuromuscular harmony of the uterus as labor begins; how the resulting tension causes the pain and impedes the orderly progress of the natural physiological processes of childbirth. He does not tell us how the fear originated, how pain first became associated with childbirth. He outlines how fear is now passed along from person to person, from generation to generation by suggestion, hearsay, public opinion, literature, religion, and the kind of obstetric care which assumes that pain is inevitable and, without seeking its cause, attempts to alleviate it with analgesics, anesthetics and artificial interference to hasten the birth of the baby.

In chapters on Education in Pregnancy and Labor, the Conduct of Labor, and Relaxation, Dr. Read describes his care and instruction of patients during pregnancy and labor to help them eliminate the fear and overcome the tension that causes the pain.

He quotes from case histories to prove that under normal conditions labor can be not only practically painless but a pleasant experience that is followed immediately after the birth of the baby by an overwhelming ecstasy with physical reactions that reduce the blood loss and hasten involution. He devotes considerable space to discussing the questions, doubts, and objections called forth by his earlier book about natural childbirth.

The human race always abandons its traditions with reluctance. The lay, no less than the professional mind, doubts revolutionary theories and practices until they are tested by several workers other than the discoverers. One can hope that *Childbirth Without Fear* will soon be followed by reports of the testing of Dr. Read's theories and practices. In the meantime, doctors, midwives, and nurses can ill afford to miss

reading this book. Dr. Read is a physician of broad experience. His convictions about the significance of the emotional factor in the mechanism of labor are based on his education in biology, physiology, and neurology, which included work with the scientific pioneers who discovered the "influence of the sympathetic nervous system upon the activities of the viscera, the causes and interpretation of painful stimuli, and the visceral reactions to emotional states." Such convictions can't be lightly discarded, particularly when the significance of the emotional factor is being emphasized in all human behavior, in all physiologic processes, in dysfunction, in pain, in disease.

HAZEL CORBIN

Applied Dietetics — By Frances Stern. (2nd ed.) Baltimore: Williams & Wilkins, 1943. 265 pp. Price, \$4.00.

This is the second edition of Miss Stern's valuable book; the first edition was published in 1936. This edition has been enlarged and greatly improved to meet changing needs and in order to include newer knowledge of the application of dietetics which has resulted from the rapid advances of this science.

This book lays down the principles for the prescription of a therapeutic diet, coördinating the findings and recommendations of the doctor, dietitian, social worker, and nurse. The normal diet is first discussed, showing that all therapeutic diets must vary from the normal according to physiological findings, which may call for a decrease or increase of the normal food constituents.

The computation of diets and menus is greatly simplified by the numerous tables and lists of equivalent foods. Food constituent values are also given for the recipes of the more common foods.

Complete outlines are given for treat-

ment of such conditions as food allergy, vitamin deficiencies, ulcer, obesity, constipation, colitis, nephritis, diabetes, and liver disorders.

The book is highly recommended for

teachers of dietetics, and is a most useful reference book for physicians, hospital and clinic dietitians and all others who have a special interest in this field.

OCTAVIA H. SMILLIE

BOOKS RECEIVED

TROPICAL NURSING. By A. L. Gregg. 2nd ed. New York: Philosophical Library, 1944. 185 pp. Price, \$3.00.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

The Peak Seems Past—In 1943 the United States experienced the highest incidence of meningococcus meningitis in the 30 years of Public Health Service morbidity experience. In 1929 (the next highest year) the case fatality ratio was about 50 per cent. In 1943 it is estimated at 18 per cent. Sulfonamide therapy is given credit for most of the difference.

ANON. Meningococcus Meningitis in the United States during 1943. Pub. Health Rep. 59, 14:469 (Apr. 7), 1944.

Odd Items Department—It seems that some swing musicians labor under the delusion that they achieve otherwise unachievable heights of virtuosity under the influence of marihuana. A group of incarcerated addicts were given a synthetic marihuana and, though their musical performance deteriorated measurably, they thought they were wonderful. I don't know what good it does to tell *you* this.

ALDRICH, C. K. The Effect of a Synthetic Marihuana-like Compound on Musical Talent as Measured by the Seashore Test. Pub. Health Rep. 59, 13:431 (Mar. 31), 1944.

Education Was Once a Private Concern—Society in general now realizes that the health of the people is as important as their education, says this medical commencement orator, who concludes with the prophetic pronouncement: universal medical service is a social necessity and cannot indefinitely be postponed.

CONKLIN, E. S. "The Doctors Dilemma" or Medical Ethics in Peace and War. Science. 77:2567:187 (Mar. 10), 1944.

Bed Rest May Be Lethal—Though this paper can scarcely be catalogued

as part of the literature of public hygiene, it will do you a world of good to read it, just to see how a medical postulate, hoary and honored with age, can be knocked into a cocked hat by the take-nothing-for-granted mind. You'll wonder how our own axiomatic assumptions will stand up if a really curious person should examine them.

DOCK, W. Use and Abuse of Bed Rest. New York State J. Med. 44, 7:724 (Apr. 1), 1944.

About the Rickettsias—In handy form, you will find here all you will probably need to know about typhus, spotted fever, tsutsugamushi and Q fevers. In this symposium are papers which treat in the same inclusive way the subjects of diarrheal diseases and the malarias. The series will prove a useful addition to your clipping library.

DYER, R. E. The Rickettsial Diseases (and two other papers). J.A.M.A. 124, 17:1165 (Apr. 22), 1944.

Young Women at Hard Work—Economic Status is the major determining factor in tuberculosis incidence in young women, concludes this study. Tuberculosis mortality is not significantly greater among employed women than among women generally of the same age and economic status. Before the war is over we may have some statistics which will cause us to qualify this generalization.

DORAN, M. V. Tuberculosis in Employed Women. Am. Rev. Tuberc. 49, 2 (Feb.), 1944.

Despite Lost Ration Books—There was no evidence found that rationing had any adverse effect upon the food habits of certain Baltimoreans, reports

this study. Young people do better by the stomachs than do their opinionated or ignorant elders.

DOWNES, J., and BARANOVSKY, A. Food Habits of Families in the Eastern Health District of Baltimore in the Winter and Spring of 1943. *Milbank Quart.* 23, 2:161 (Apr.), 1944.

When Johnny Comes Marching Home—Malarious—Skeleton teams of entomologists and engineers are in the making by the U. S. Public Health Service to survey, inspect, and institute mosquito control measures where malaria carriers are present. These teams will be available for assignment to work under state direction. This would seem to be an aid which wide-awake administrators would book tentatively and in advance.

FREEBORN, S. B. Problems Created by Returning Malaria Carriers. *Pub. Health Rep.* 59, 11:357 (Mar. 17), 1944.

Maybe It's Because the Rich Are Getting Poorer!—That ancient gag-song "the rich get richer and the poor get children" no longer is true to life (in either direction) apparently. This study of birth rate behavior among New York City's white population finds a continuing trend toward contracting differentials in fertility among rich and poor. It is in the higher income groups that the increase in fertility is occurring.

JACOBSON, P. H. The Trend of the Birth Rate among Persons on Different Economic Levels, City of New York, 1929-1942. *Milbank Quart.* 23, 2:131 (Apr.), 1944.

Compound Tincture of Round Table—Annotating an ably edited digest surpasses in futility the gilding of gold refined to 24 karat. So, it is enough here to point out that this digest is one to be read thoughtfully by every living soul among us.

KISER, C. V. Implications of Population Trends for Post-war Policy. *Milbank Quart.* 23, 2:111 (Apr.), 1944.

Healthful Housing—Redevelopment of substandard urban areas is our number one post-war civic problem says the writer who introduces what constitutes another series of outstanding articles on this public health hazard with which all of us, no matter what our particular job may be, should be concerned.

LASKER, L. D. The Call of Our Cities (and seven related papers). *Survey Graphic.* 33, 4:197 (Apr.), 1944.

Nursing Insurance—Either nursing is a luxury service for the rich, or the poor are denied something they should have. Though no one can foretell if he will be sick and need nursing services during the coming year, it is possible to predict in any community the amount of nursing care which will be needed during that period. Hence, the insurance principle is applicable. Nurses, says this authority, have good cause to interest themselves in the whole movement to distribute costs of illness, and, he adds, the time to plan for post-war adjustments is now.

MOUNTIN, J. W. Suggestions to Nurses on Post-war Adjustments. *Am. J. Nurs.* 44, 4:321 (Apr.), 1944.

Anent "Cold Sores"—This may not be new to you, but it seems that herpes simplex infection normally takes place in early childhood, and that the virus remains latent presumably in the cells near the circumoral site of the primary infection, ready to pop out under the stimulus of excessive light, heat or cold, or another disease. Adult primary infection is unusual. Live and learn, say we.

NAGLER, F. P. O. A Specific Cutaneous Reaction in Persons Infected with the Virus of Herpes Simplex. *J. Immunol.* 48, 4:213 (Apr.), 1944.

In Memorium to the Word "Level"—Lack of progress in the effective control of gonorrhea, should

have been the title of this whole-somely frank discourse upon bargain-basement dosing methods. The paper is strong medicine for v. d. officers, but it has a lesson in it for all of us. By its resort to the phrase "at the dispensary level" this paper reduces to the ultimate level of scientific gargon (at the medical paper level) that sadly overworked word "level"—and this barb is leveled at all the writers of whatever level who prate about things "at the state level" or "at a nuisance level." Please, let's all let "level" die awhile—level!

PELOUZE, P. S. Progress in the Wartime Management of Gonorrhea. *Ven. Dis. Inform.* 25, 2:42 (Feb.), 1944.

And Are You One of the 2,500,000?—At the end of last year the Red Cross had collected 5 million pints of blood (from about half that number of donors). Through thirty-five centers approximately 45 per cent of the country's population has the opportunity to donate this greatest of all life-saving elements for our wounded

soldiers and sailors. Because of experienced personnel and standardized methods, operational losses are minimal.

TAYLOR, E. S., and HEISS, M. E. American Red Cross Donor Service. *J.A.M.A.* 124, 16:1100 (Apr. 15), 1944.

Plague—Sulfadiazine cured experimental infections of plague in guinea pigs and, because the disease in pigs and man is so similar in its course, the authors are led to speculate upon the value of the drug in the treatment of human plague.

WAYSON, N. E., and MCMAHON, M. C. Plague. Sulfadiazine Treatment of Guinea Pigs Infected by Artificial Methods or by Flea Transmission. *Pub. Health Rep.* 59, 12:385 (Mar. 24), 1944.

Susceptibility to Rheumatic Fever Is a Recessive Characteristic—This is about the potentially rheumatic family as a public health objective. Medical supervision of the rheumatic patient is not the end of the hygienist's responsibility.

WILSON, M. G. Hereditary Susceptibility in Rheumatic Fever. *J.A.M.A.* 124, 17:1188 (Apr. 22), 1944.

ASSOCIATION NEWS

SECOND WARTIME PUBLIC HEALTH CONFERENCE AND SEVENTY-THIRD ANNUAL BUSINESS MEETING AMERICAN PUBLIC HEALTH ASSOCIATION

New York, N. Y., October 3-5, 1944

Headquarters: Hotel Pennsylvania

MEETING OF THE COMMITTEE ON PROFESSIONAL EDUCATION

THE Committee on Professional Education of the Association met on April 21 in New York under the Chairmanship of W. P. Shepard, M.D., of San Francisco. This was the first meeting of the committee since its reorganization at the time of the War-time Conference in New York last October. At that time the committee was dissolved and reconstituted by Governing Council action to consist of 12 members appointed for 3 year terms, 4 members retiring each year. As it now stands the committee is well equipped to carry out its immediate plans and to chart an ambitious course for the future.

Among the many encouraging reports received dealing with recent progress was one from the Subcommittee on Merit Systems of which George H. Ramsey, M.D., of Ann Arbor, Mich., is Chairman. Believing that the membership will wish to know what goes on behind the scenes so far as the preparation of an examination is concerned, excerpts from Dr. Ramsey's report follow.

"As prepared by the Merit Systems Unit (the staff employed to carry on this project), a completed examination consists of a large

number of multiple choice questions or items. A single examination may contain 200 or more items.

"The customary procedure in assembling an examination begins with the appointment of a consultant who is a specialist in the field to be covered. He takes part in the collection and preparation of items and in the assembling of examinations.

"Experience has shown that the best items come from workers in positions similar to that for which the examination is being held, rather than from those in directing or academic positions. Accordingly, the consultant and other members of the Merit Systems staff request field workers to construct items and teach those who comply how items should be prepared. Field workers serving as item constructors are paid a small fee for each acceptable item. More than 140 field workers have already served as item constructors.

"Items collected in the field are submitted to a group of reviewers, who are directors, or are in supervisory positions in the field to be covered. They criticize each item and pass judgment as to its validity and practical value. Approximately 147 directors or supervisors in health agencies have served without compensation as reviewers up to the present time.

"Items approved are revised, edited, and placed in suitable form by the consultant, the psychometrician, and other members of the staff. A record is kept of each item showing where and when it has been used and success or failure in giving the correct answer. In

AMERICAN PUBLIC HEALTH ASSOCIATION COMMITTEE ON PROFESSIONAL EDUCATION MEETING

APRIL 21, 1944

Left to right: Standing: Reginald M. Atwater, M.D., *Secretary*, New York N. Y.; W. W. Bauer, M.D., Chicago, Ill.; Wilson G. Smillie, M.D., New York, N. Y.; Robert D. Defries, M.D., Toronto, Ont.; George H. Ramsey, M.D., Ann Arbor, Mich. Seated: Lowell J. Reed, Ph.D., Baltimore, Md.; Ralph E. Tarbett, C.E., Washington, D. C.; John Sundwall, M.D., Ann Arbor, Mich.; W. P. Shepard, M.D., *Chairman*, San Francisco, Calif.; Pearl McIver, R.N., Washington, D. C. (Absent when photo was taken: Gaylord W. Anderson, M.D., Washington, D. C.; Edward S. Godfrey, Jr., M.D., Albany, N. Y.; Ernest L. Stebbins, M.D., New York, N. Y.; Clair E. Turner, Dr.P.H., Cambridge, Mass.)

assembling items for an examination, the qualifications for admission are taken into account.

"Material covering positions in the following public health activities thus far assembled and ready for immediate use are: General administration (health officers), 800 items; public health nursing, 1,500 items; environmental sanitation, over 200 items; and laboratory service, 900 items.

"Greatest progress has been achieved in the field of public health nursing. Sixty-five examinations purchased from the Association have been held in 15 states and one city and arrangements for examinations in several other states are pending. Examination material has been prepared with consultation and assistance from appropriate outside agencies in two specialized fields, nurse midwifery and orthopedic nursing.

"Thirteen examinations covering laboratory positions have been purchased by three states and one state has purchased examinations for three positions in environmental sanitation.

"It is expected that work in the field of environmental sanitation will be expanded at an early date to cover positions in public health engineering, and plans are under way for the preparation of examination material covering positions in venereal disease control.

"When first organized at the request of the

Children's Bureau and the United States Public Health Service, the Merit Systems Unit undertook to fulfil an urgent need for examination material. This need has been met in several branches of public health work, and examination material of a high quality, better than can be obtained from most other sources, is available. An orderly procedure for preparing examinations has been adopted and successfully put into effect. The Unit is organized and equipped to function smoothly in its original task and to meet increased demands for examination material at the end of the war.

"The Association has engaged in several other merit system activities besides the preparation of examinations. These have had to do with general promotion and making known the necessity for, and the value of, adequate systems for the selection of personnel. A member of the Merit Systems staff has spent considerable time in the field, holding discussions and conferences with numerous agencies and with all national nursing organizations with the view to promoting a better understanding of the basic principles of merit system activities. There is need for further interpretation of the place and functions of merit systems to both lay and professional groups, particularly in states where such systems have been recently organized.

"Obviously, consideration must soon be given to broadening the scope of the Association's activities in this field. There are many specific problems in the selection of personnel and in the evaluation of services which demand research and study. Also requests for assistance from state merit system agencies in other fields of endeavor in addition to the preparation of examinations are to be anticipated. It is to be hoped that funds can be made available so that the Merit Systems Unit will be able to expand its work according to future needs and to undertake special studies of new problems that arise."

A report on the Educational Qualifications of School Physicians, prepared by a Subcommittee of which Charles C. Wilson, M.D., of New York, is Chairman, was received with interest. It was felt desirable to consult with other interested groups such as the National Education Association and the American Association of School Administrators before proceeding with publication of the report. The committee welcomes comments and criticisms from interested outside agencies as well as from the membership of the Association before seeking approval of the Governing Council on all its reports. This one is expected to be published in the September JOURNAL.

Among essential health services there are specialized activities, each of which calls for a medical administrator who is a physician qualified both in his particular specialty and in the general field of health administration. Such activities are in the fields of maternal and child health, tuberculosis control, venereal disease control, cancer control, mental hygiene, and industrial hygiene. For medical personnel engaged in these activities the Committee on Professional Education has prepared a report entitled "The Educational Qualifications of Medical Administrators of Specialized Health Activities." It has already received the approval of the committee and will be published in an early issue of the JOURNAL. It has been suggested

that consideration might eventually be given to the matter of qualifications for medical administrators in the field of public medical services and perhaps also in hospital administration. This the committee has under advisement and it may well be that a statement will eventually be formulated.

It will be recalled that in 1939 the Governing Council approved a report on the Educational Qualifications of Health Officers. Within the last year it has become apparent that, with the changing times, there is need for a more up-to-date report on this subject. Accordingly a revision has been prepared and has had careful consideration. It will appear in the JOURNAL within the next few months prior to its submission to the Governing Council for approval.

A report on the Educational Qualifications of Executives of Voluntary Health Agencies was presented to the committee which points out that there are some 3,000 voluntary health associations in the United States. Because of the notable trend in voluntary health agencies to broaden their health programs rather than to concentrate on a particular specialized health problem, the report prepared by a subcommittee of which George J. Nelbach of New York is Chairman, outlines the broad basic training which an executive should have. It is anticipated that its publication will prove of interest to a large number of persons.

The Educational Qualifications of Public Health Dentists was another report received for further consideration. After the necessary editorial changes this will be published in the JOURNAL.

A revision of the report on the Educational Qualifications of Professional Personnel in Sanitation, originally approved by the Governing Council in 1937, was presented by the Referee, Ralph E. Tarbett, C.E., of Washington, D. C. This report deals only with per-

sonnel on the graduate level, whereas the earlier statement covered those on the subprofessional level as well. After further study the report will be circulated for comments and subsequently published.

The matter of field training of public health personnel was the subject of a report presented by Wilson G. Smillie, M.D., of New York, Chairman of the subcommittee of the same name. Discussion brought out the need for the greater utilization of such centers and the proposal that an agency like the American Public Health Association might at some future time attempt to evaluate existing centers.

Of prime concern to the Committee on Professional Education is the serious need for adequate compensation for professional personnel in public health, particularly in view of the higher standards which have been established along the lines of qualifications and experience. The Governing Council and the Executive Board have gone on record as encouraging the committee to take whatever steps seem desirable to attain this objective. Various professional societies have already been approached with a view to securing their coöperation in assuring remuneration comparable to that for similar skilled professional services within the community. The Officers of the Association's Sections have been asked whether they would be willing to undertake a study of the problem among their own members. When all the facts are in hand it is hoped that a united front of all professional pub-

lic health workers can be presented.

A request from the National Conference for Coöperation in School Health Education for coöperation in reconciling the reports which have been issued by various agencies regarding functions and qualifications of school physicians, nurses, teachers, and other school health personnel was considered. The committee expressed its willingness to coöperate in bringing about the desired coördination.

The desirability of certifying schools of public health at some future date was again considered. While there is general agreement as to the necessity for such an undertaking by an appropriate agency, the committee felt that such a project must wait until after the war.

For several years the committee has deplored the multiplicity of degrees and certificates awarded by universities in the United States and Canada in the graduate field of public health. Encouragement was expressed by the decline in this trend last year. During the academic year 1942-1943, 20 different degrees and certificates were awarded as compared with 27 in the previous academic year.

The committee was gratified with the report that since 1936 it has distributed more than 20,000 reprints of reports dealing with educational qualifications, and it expressed satisfaction with the wide acceptance and, in many instances, actual application of these standards.

ISABEL LANDY FANTEL

Associate Secretary

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

M. C. Adamson, M.D., 8620 100th St., Edmonton, Alberta, Canada, Health Officer, Clover Bar Health Unit
 Casimir E. Bielecki, M.D., 35 Main St., Norwich, Conn., Health Officer
 Harry M. Boyarsky, M.D., 450 Center St., Wallingford, Conn., Health Officer
 Arthur E. Burke, M.D., Central Ave., Ayer, Mass., District Health Officer
 Helen Evarts, M.D., 3 Concord Ave., Cambridge, Mass., Senior Physician, Middlesex County Sanatorium
 Marion G. Fisher, M.D., District Health Dept., Morristown, Tenn., Director
 Winter R. Frantz, M.D., City Hall, Cumberland, Md., Health Officer, Allegany County Health Dept.
 Gerhard Hartman, Ph.D., Newton Hospital, Newton Lower Falls 62, Mass., Director
 Blas C. Herrero, M.D., San Juan Municipal Hospital, San Juan, Puerto Rico, Director of Health and Charities
 Edward W. Kunekel, M.D., 108 W. Cary St., Richmond, Va., Medical Director, Richmond Municipal Hospital
 Herbert A. Laidman, D.O., Health Officer, Glen Rock, N. J.
 Wendelin G. Luckner, M.D., 81 E. Main St., Stafford Springs, Conn., Health Officer, Union, Conn.
 Frederiek McVey, M.D., 516 Talbot Ave., Dorehester, Mass., Medical Inspector, Boston Health Dept.
 K. I. Murray, M.D., C.M., Roxy Bldg., Lethbridge, Alberta, Canada, Medical Officer of Health
 Nelson Podolnick, M.D., Fairfax County Health Dept., Fairfax, Va., Health Officer
 DeWillett S. Puffer, M.B., D.P.H., City Bldgs., Kingston, Ontario, Canada, Medical Officer of Health
 Reuben Rothblatt, M.D., 672 Main St., Wilimantic, Conn., Health Officer
 Gustave G. Schram, M.D., Territorial Board of Health, Wailuku, Maui, Hawaii, County Health Officer
 Rudolfo Verastegui-Lopez, M.D., Clavigero No. 8, Jalapa, Ver. Mexico, Chief, Jalapa Sanitary Unit
 Thomas F. Walker, M.D., 206 Medical Arts Bldg., Great Falls, Mont., Health Officer, City-County Unit
 Harry G. Wyer, M.D., 750 Washington St.,

Brookline, Mass., South Metropolitan District Health Officer, State Dept. of Health

Laboratory Section

Cleon W. Abbott, 168 Dakota St., San Francisco, Calif., Junior Scientific Aide, U. S. Public Health Service
 Dr. Mark Barker, Dept. of Agriculture, Confederation Bldg., Ottawa, Ontario, Canada, Veterinary Director-General, Health of Animals Division
 Orlando Bonilla-Soto, School of Tropical Medicine, San Juan, Puerto Rico, Asst. Instructor in Bacteriology, Dept. of Public Health
 Alberta M. Bonnett, 328 W. Mulberry, Fort Collins, Colo., Junior Bacteriologist, Weld County Public Health Dept.
 Mattie Carter, State Hygienic Laboratory, Jackson, Miss., Bacteriologist
 Emil Freienmuth, 1722 Belvoir Court, Topeka, Kan., Bacteriologist, City Health Dept.
 Catherine A. Gaffney, A.M., 101 W. 84th St., New York 24, N. Y., Bacteriologist, Kings County Hospital, Brooklyn, N. Y.
 Louis P. Gebhardt, M.D., University of Utah, School of Medicine, Salt Lake City, Utah, Professor of Bacteriology
 Lt. James C. Harris, Sn.C., Medical Inspector's Office, Mason General Hospital, Brentwood, N. Y., Asst. Medical Inspector
 John J. Henlein, Jr., 1410 Byron St., Chicago, Ill., Bacteriologist, Loyola Medical School
 H. Eugene Hyson, St. Anthony's Hospital, Rockford, Ill., Supervisor and Bacteriologist, Clinical Laboratory
 Samuel Jacobson, Ph.D., New Haven Water Company, New Haven 6, Conn., Chemist
 J. Garth Johnson, Ph.D., 404 S. Summit St., Iowa City, Iowa, Principal Chemist, State Dept. of Health
 George Klein, 412 E. 5th St., Austin, Tex., Asst. Bacteriologist, State Dept. of Health
 Sonya E. Lignell, 1764 S. 3rd East, Salt Lake City, Utah, Chief Technician, Salt Lake General Hospital
 Lt. Col. Carl J. Lind, Jr., M.C., Walter Reed General Hospital, Washington 12, D. C., Chief of Laboratory Service
 Col. Loren D. Moore, M.C., 4th Service Command Laboratory, Fort McPherson, Ga., Commanding Officer
 Major Samuel J. Penchansky, M.C., Station

- Hospital, Keesler Field, Miss., Chief of Laboratory Service
- Americo Pomales-Lebron, Ph.D., Dept. of Bacteriology, School of Tropical Medicine, San Juan, Puerto Rico, Asst. Professor of Bacteriology
- Glynne L. Rocha, M.D., Avenida Presidente, Wilson 228, Rio de Janeiro, Brazil, S. A., Physician to the National Service of Leprosy, Brazilian Dept. of Public Health
- O. C. Sieverding, 1179 Main St., Hartford, Conn., Asst. Director, Bureau of Laboratories, State Dept. of Health
- Florence M. Stone, Ph.D., 248 Baltic St., Brooklyn, N. Y., Director, Bacteriology Laboratory, Long Island College of Medicine
- Marjorie Van Vranken, 2246 Stuart St., Denver, Colo., Bacteriologist, State Board of Health
- Max Wachstein, M.D., 22 Jackson Ave., Middletown, N. Y., Director of Laboratories, Horton Memorial Hospital

Vital Statistics Section

- Richard C. Brewer, 12 Capitol Square, Atlanta, Ga., Director, Div. of Information and Statistics, State Dept. of Public Health

Engineering Section

- Lewis D. Anderson, Box 245, Hilton Village, Va., Sanitation Officer, State Health Dept.
- Vinton W. Bacon, 41 Exchange Place, Atlanta, Ga., Asst. Sanitary Engineer (R), U. S. Public Health Service, Typhus Control Unit
- Howard B. Bishop, Box 118, Summit, N. J., President, Human Engineering Foundation
- Richard G. Bond, M.S., State Dept. of Health, Des Moines, Iowa, Asst. Engineer
- Lt. Elias J. Candel, Sn.C., 106th Malaria Control Unit, Camp Plauche, New Orleans 12, La., Sanitary Engineer
- Robert L. Caviness, Box 2096, Winston Salem, N. C., Senior Engineer, Forsyth-Stokes-Davie-Yadkin Health Dist.
- Kenneth A. Diederichsen, 2370 Soto St., San Diego 7, Calif., Housing Inspector, City Health Dept.
- Frank T. Dubyne, Room 852, U. S. Customhouse, 610 Canal St. S., Chicago, Ill., Asst. Sanitarian, U. S. Public Health Service
- D. Raymond Erion, 605 High St., Milford, Ohio, Supt., Milford Water Works
- Pedro E. Hernandez-Vega, Box 259, Camuy, Puerto Rico, Student, School of Tropical Medicine
- William D. Lewis, 2000 Massachusetts Ave.,

- N.W., Washington, D. C., Asst. Sanitarian (R), U. S. Public Health Service
- G. G. Loftin, M.A., 211 South Clinton, Dallas, Tex., Sanitary Inspector, Dallas Health Dept.
- Frank W. Lovett, 300 W. Pershing Rd., Chicago, Ill., Engineer, Link-Belt County
- Carroll C. McDaniel, Chicago Bridge & Iron Company, Seneca, Ill., Sanitary Engineer
- John C. McPheeters, DelMonte Hotel, Del Monte, Calif., Rodent Control Officer, State Dept. of Public Health
- Joseph F. O'Brien, 312 Brierwood, Ann Arbor, Mich., Sanitarian, U. S. Public Health Service
- Loyal C. Peckham, City-County Health Unit, Boise, Idaho, Asst. Sanitarian (R), U. S. Public Health Service
- Camilo Pizarro, C.E., P. O. Box 800, Central 40-5 Piso of 56, Santiago, Chile, S. A., Member of Board, Garrido, Garcia Burr and Company
- Edmund R. Price, 4037 Locust, Kansas City 4, Mo., Passed Assistant Sanitarian, U. S. Public Health Service

Industrial Hygiene Section

- Capt. Robert H. Duguid, M.C., 1206 Sautee St., Los Angeles, Calif., Director, Industrial Medical Program, U. S. Army
- Gertrude R. LeMieux, 1911 4th Ave. N., Birmingham 3, Ala., Chemist, Industrial Hygiene Division, State Health Dept.
- Abraham Mirkin, Ph.D., 230 E. 12th St., New York 3, N. Y., Director, Mirkin Analytical and Pathological Laboratory
- Russell H. Scott, 903 Smith Tower, Seattle 4, Wash., Industrial Hygienist, Div. of Industrial Hygiene, State Health Dept.
- John A. Zapp, Jr., Ph.D., 6360 Sherman St., Philadelphia 44, Pa., Technical Aide, National Defense Research Committee, Office of Scientific Research and Development

Food and Nutrition Section

- Bertlyn Bosley, State Board of Health, Raleigh, N. C., Principal Nutritionist
- Bertha Burke, A.M., Harvard School of Public Health, 55 Shattuck St., Boston, Mass., Assoc. in Nutrition, Dept. of Child Hygiene
- M. Audrey Holt, 15 Marlborough St., Boston 5, Mass., Student, Harvard School of Public Health
- Almeda King, M.S., 45 Washington St., Ayer, Mass., Nutritionist, State Dept. of Public Health
- Mary W. Thrasher, M.S., State Board of

Health, Raleigh, N. C., Senior Nutritionist
Andromache Tsongas, 55 Shattuck St., Boston, Mass., Student, Harvard School of Public Health

Maternal and Child Health Section

Moses Cooperstock, M.D., Northern Michigan Children's Clinic, Marquette, Mich., Medical Director, Cardiac Program, Michigan Crippled Children's Commission
J. V. Cresci, M.D., 182 Clinton St., Brooklyn 2, N. Y., Physician, Maternal and Child Hygiene Dept., New York City Health Dept.
Lt. Col. J. Leonard Moore, M.C., Hq. Army Air Forces, ADTIC, 25 Broad St., New York 4, N. Y.
Dean W. Roberts, M.D., 513 N. Wolfe St., Baltimore, Md., Chief, Bureau of Child Hygiene, State Health Dept.
Eugene Smith, M.D., 714 Eccles Bldg., Ogden, Utah, Staff Pediatrician, State Dept. of Health
Pauline G. Stitt, M.D., Board of Health, Honolulu, Hawaii, Asst. Director, Bureau of Maternal and Child Health

Well qualified public health engineer seeks responsible position in New York metropolitan area. **E-480**

Sanitary Engineer, C.E. 22 years' experience as sanitary engineer, 14 as director in state health department, now employed. Desires change. Location immaterial. **E-481**

LABORATORY

Research bacteriologist. Unusually trained and experienced woman bacteriologist and serologist now occupying responsible position in state laboratory seeks research work of permanent character. **L-468**

Water chemist, bacteriologist, M.S. degree in Sanitary Chemistry. Age 36, draft exempt. Eight years' experience in state laboratory working on water, milk and sewage. Prefers Midwest or Pacific Northwest location. **L-469**

Research bacteriologist-veterinarian, now in civil service, desires change to direct or indirect war work. P-3 classification. Considerable laboratory and field experience. Used to foreign travel; will go anywhere. Steady hard worker. **L-470**

MISCELLANEOUS

Public Health Nurse. B.S. in nursing, William and Mary College, age 53, seeks position as coordinator of public health nursing, educational director, or director student nurse public health program. Prefers Middle Atlantic States. **M-452**

NEWS FROM THE FIELD

STATE AND TERRITORIAL HEALTH OFFICERS ASSOCIATION OPPOSES FEDERAL COMMISSION FOR INDUSTRIAL SAFETY

At its March meeting, in Washington, the State and Territorial Health Officers Association passed the following resolution:

WHEREAS it appears that a Bill (H.R. 4371) introduced in the House of Representatives under date of March 9, 1944, proposes the extension of services in the Department of Labor by creating therein a Commission for Industrial Safety, and

WHEREAS it further appears that the creation of a Commission for Industrial Safety in the Department of Labor would duplicate activities already provided for in the U. S. Public Health Service for this purpose, and therefore would be wasteful of public moneys, and

WHEREAS furthermore the activities of the proposed Commission for Industrial Safety would tend to interfere with similar services now carried out in various states and state departments, now therefore be it

RESOLVED that the Association of State and Territorial Health Officers hereby declares itself opposed to the Bill in question and reaffirms the opposition which it expressed against Bill H.R. 2800, a similar Bill introduced in the House of Representatives in 1943.

NURSING STUDY PUT ON GRADUATE LEVEL

John S. Gibbs, Jr., President of the hospital board of The Johns Hopkins Hospital, has announced that a baccalaureate degree from an accredited college will be required of all candidates for admission to The Johns Hopkins Hospital School of Nursing, starting with the October term.

He explained that entrance requirements were being raised to meet "the great demand for graduate nurses of superior preparation in the many responsible positions in education and administration, in institutions, in the

fields of public health and in other nursing services." The change would also make it easier for the school to map a training program.

The hospital school "will continue its participation in the program of student nurse enrollment fostered by the Government and it is confidently expected will continue to enroll large classes during the war." Of the present 453 students, 373 are members of the United States Cadet Nurse Corps.

BIENNIAL NURSING CONVENTION AND EXPOSITION

The biennial convention of the American Nurses' Association, the National League of Nursing Education, and the National Organization for Public Health Nursing will be held in Buffalo, N. Y., June 5-8. Exhibits as well as principal meetings will be held in the Buffalo Memorial Auditorium, and headquarters are designated as follows: ANA—Hotel Statler, NLNE—Hotel Lafayette, NOPHN—Hotel Buffalo.

NEW YORK OPENS RAPID TREATMENT CENTER AT BELLEVUE HOSPITAL

The Bellevue Hospital Rapid Treatment Center was opened on April 1 in New York City as a war-connected project made possible through the cooperation of the Federal Works Agency and the U. S. Public Health Service with the New York City Department of Hospitals. Among the speakers participating at the dedication were Mayor F. H. LaGuardia, J. R. Heller, Jr., M.D., Assistant Surgeon General, U. S. Public Health Service, in charge of venereal disease control, and Edward M. Bernecker, M.D., Commissioner of Hospitals. Federal Latham Act funds totaling \$575,000 were made available, of which \$290,000 were

for construction and the remainder for equipment and maintenance. Federal maintenance is expected to continue for the duration, after which New York City Department of Hospitals will have the benefit of the construction and equipment. For syphilis and treatment will be in general arsenotherapy combined with fever. When and if penicillin is available it will be used. For gonorrhea patients, sulfonamide drugs will be used with fever therapy for those patients who do not respond to the sulfa drugs.

Cornelius T. Stepita, M.D., Surgeon, U.S.P.H.S., has been assigned as administrator of the Treatment Center under the direction of the Medical Superintendent of Bellevue Hospital. One hundred fifty employees including nurses, dietitians, medical social workers, educational and recreational staff, laboratory workers, hospital helpers, clerical staff and maintenance workers are included. Evan W. Thomas, M.D., Chief Syphilologist at Bellevue Hospital, and Alfred Cohn, M.D., in charge of gonococcus research for the Department of Health, will direct the treatment of patients.

An inpatient and an outpatient service at Bellevue will have a 200 bed capacity, and a rehabilitation program will be conducted in buildings of the former convalescent day camp on Welfare Island, with 100 bed capacity. This rehabilitation program will be operated in conjunction with the Board of Education. It will include vocational courses especially aimed at employment in war industries and recreation facilities for patients. After-care supervision will be the responsibility of medical social workers and psychiatric service where necessary will be provided by Bellevue Hospital.

PUBLIC HEALTH IN PUERTO RICO

Under the auspices of the Puerto Rico Public Health Association a recent 2

day meeting was held at San Juan as well as a meeting under the auspices of the public authorities concerned with venereal disease occupying another day.

According to Professor Earle B. Phelps of Columbia University, who has been teaching at the School of Tropical Medicine, there are about 80 students in public health at the school this year in the classifications of health officers, sanitarians, public health nurses, and public health technicians. A group of sanitary inspectors from Haiti took a short course recently. The school is under the direction of Dr. Morales Otero.

DR. STUART MUDD HONORED FOR BLOOD PLASMA WORK

Stuart Mudd, M.D., Professor of Bacteriology at the University of Pennsylvania, has been awarded the annual William Guggenheim honor cup by the University of Pennsylvania Club of New York City. He was selected to receive the award for 1943-1944 "for his outstanding services in his chosen profession, and particularly in the field of blood plasma development with special reference to the system now used by the armed forces of the United States in all battle areas."

SOUTH DAKOTA'S PUBLIC HEALTH PERSONNEL

The recent edition of South Dakota's *Health Highlights* indicates that the following persons are now identified with the State Board of Health at Pierre:

Gilbert Cottam, M.D., Superintendent
 Antony Triolo, M.D., M.P.H., Director of Crippled Children and Child and Maternal Health

 Glen Hopkins, B.S., Acting Director Sanitary Engineering
 B. S. Levine, M.S., Ph.D., Director of State Laboratories
 Alice Olson, R.N., Director Division of Public Health Nursing

Irvin R. Vaughn, B.A., Director Public Health Education, Assistant Director Vital Statistics
 T. A. Evans, M.A., State Milk Specialist
 Esther Kempter, Director of Records and Accounts, Personnel Officer
 Howard Selvig, M.A., Supervisor Merit System

FLORIDA PUBLIC HEALTH ASSOCIATION

The Florida Public Health Association has elected the following officers to serve for the ensuing year:

President—A. P. Black, Ph.D.
First Vice-President—W. W. Rogers, M.D.
Second Vice-President—Dr. Lucille Marsh
Secretary-Treasurer—E. M. L'Engle, M.D.

PUBLIC HEALTH TRAINING PROGRAMS FOR LATIN AMERICAN GUESTS

A recent report of the Coördinator of Inter-American Affairs indicates that of 215 training programs for Latin American visitors under the auspices of the Coördinator, the following concerned the field of public health:

Biostatistics	2
Blindness prevention	2
Dentistry	7
Health museums	1
Malariology	2
Nursing administration	3
Nutrition	6
Parasitology	1
Public Health	38
Public Health Education	16
Public Health Laboratory	6
Public Health Nursing	10
Quarantine Service	1
Sanitary Engineering	45
Tuberculosis Administration	5
Tuberculosis Research	3
Veneral Disease Control	5
Vital Statistics	1

Dr. Charles E. Shepard of the Division of Health and Sanitation is in charge of the Institute Training Program.

VANDERBILT CONFERS GRADUATE DEGREES IN PUBLIC HEALTH

According to the *Journal of the American Medical Association*, Vanderbilt University recently conferred the

degree of Master of Public Health on two candidates, marking the first time in the history of the university that such a degree has been granted. Dr. F. Olason of Iceland and Dr. F. Plotke of Illinois were the recipients of the degrees. Dr. Olason is reported to be a student at the Harvard School of Public Health under a Fellowship from the Commonwealth Fund.

THE NATIONAL NUTRITION FOUNDATION, INC. ANNOUNCES GRANTS OF \$130,000 FOR RESEARCH PROJECTS IN NUTRITION

Thirty-three colleges and universities in the United States and Canada will receive renewals of grants for 31 research projects already in progress; and Harvard, Yale, and Cornell will receive funds for new studies.

Dr. C. G. King, Scientific Director of the Foundation, has stated that the most valuable research projects made possible by the Foundation's grants thus far have been "those dealing with army rations, human protein requirements, maternal and infant nutrition, dental caries, and human vitamin requirements."

The new grants are as follows:

Harvard University—for training physicians in the human and public health aspects of nutrition.

Yale University—in support of maternal and infant nutrition studies based on carefully controlled nutrient intakes of primates.

Cornell University—for study of the biochemical mechanism of converting starches and sugar into fat.

A.P.H.A. BOOKS MICROFILMED FOR CHINA

Through the auspices of the American Bureau for Medical Aid to China, volumes on *Standard Methods for the Examination of Dairy Products*, *Standard Methods for the Examination of Water and Sewage*, and *Diagnostic Procedures and Reagents* have been microfilmed and flown to China for the

use of the National Institute of Health in Chungking.

This project is in addition to the microfilming of current issues of the *American Journal of Public Health* and other publications which are regularly sent to China for the benefit of medical schools and official public health agencies in several parts of free China.

UNIVERSITY OF CALIFORNIA AT
BERKELEY OPENS SCHOOL OF
PUBLIC HEALTH

President Robert G. Sproul of the University of California, has announced that a School of Public Health has now been established on the Berkeley campus with Walter H. Brown, M.D., Chairman of the Department of Hygiene, as acting dean. The school was set up by the Board of Regents after the State Assembly passed a bill appropriating funds. According to President Sproul, it is an answer to the intensified wartime demand for well trained personnel to fill the depleted staffs of county health offices in California and other western states, which fear a shortage of facilities for meeting serious public health danger.

Planned as a University-wide undertaking using resources of all campuses, the school is being organized as a co-operative enterprise, involving the participation of several other schools and departments, including the fields of medicine, medical research, education, nursing, home economics, and sanitary engineering. The Department of Hygiene will be renamed the Department of Public Health and function as part of the school.

Provision for courses and curricula on both undergraduate and graduate levels is contemplated, and plans will be developed regarding graduate training of health officers, epidemiologists, public health engineers, industrial hygienists, and other specialists.

The first official activity of the school

will be a special training course for sanitarians to meet the needs of the State Department of Health in the war emergency.

DR. WILBUR A. SAWYER APPOINTED
HEALTH DIRECTOR OF UNRRA

It was announced in Washington on April 25 that Wilbur A. Sawyer, M.D., of New York, N. Y., who for nine years has been the Director of the International Health Division of the Rockefeller Foundation, and who formerly was State Health Officer of California, has been appointed Director of the Health Division of the United Nations Relief and Rehabilitation Administration. Dr. Sawyer is scheduled to retire from the International Health Division next August. James A. Crabtree, M.D., of the U. S. Public Health Service staff, has been acting director of the Health Division of UNRRA.

AMERICAN ASSOCIATION FOR HEALTH,
PHYSICAL EDUCATION AND
RECREATION

The American Association for Health, Physical Education and Recreation, at its recent 4 day convention in New York City, announced the election of the following officers:

President—William L. Hughes, Columbia University, New York, N. Y.

President-elect—Helen Manley, University City, Mo.

Vice-President of Health Education Division—Dorothy Nyswander, Ph.D., Washington, D. C.

Vice-President of Physical Education Division—Dr. Harry A. Scott, Houston, Tex.

Vice-President of Recreational Division—Carl L. Nordly, University of Minnesota, Minneapolis

PSYCHOSOMATIC MEDICINE FUND

The National Committee for Mental Hygiene, New York, N. Y., has announced the establishment of a fund for research in psychosomatic medicine. According to the announcement, the purpose is to stimulate and to subsidize

research in the psychosomatic aspects of the diseases chiefly responsible for disability and death. The director of the fund will be Dr. Edward Weiss of Philadelphia. Members of the Project Committee include Dr. Charles M. Aldrich, Dr. Franz Alexander, Dr. Stanley Cobb, Lt. Col. William C. Menninger, and Dr. John Romano. The fund will be administered under the direction of Dr. George S. Stevenson, Medical Director of the National Committee for Mental Hygiene, New York, N. Y.

CIVILIAN PENICILLIN QUOTA SET

The War Production Board has recently announced that ten billion units of penicillin can be allotted to civilian use under a plan of distribution through more than 1,000 hospital outlets which have been designated as depots by the WPB.

Although unable to set an exact date, it is anticipated that deliveries would soon begin and the Office of Civilian Penicillin Distribution (OCPD) has been established in Chicago. The March production totals were thirty-five billion units.

SOUTH CAROLINA CONDUCTS WATER WORKS SHORT SCHOOL

The South Carolina Water Works Association and the South Carolina State Board of Health conducted a Water Works Short School at Clemson College, April 10 and 11. More than 50 water plant operators registered for courses and visitors brought up the total attendance to over 75. At a business meeting of the association held in connection with the school, it was voted to change the name of the organization to the South Carolina Water and Sewage Works Association and to revise the Constitution and the general program of the association so that sewage works operators may be included as members.

NEW BILL WOULD ESTABLISH DIVISION OF TUBERCULOSIS CONTROL IN THE U.S.P.H.S.

H. R. 4615 and S. 1851, introduced by Mr. Bulwinkle in the House, and Mr. Thomas in the Senate in April, has been approved by the National Tuberculosis Association and unanimously endorsed by the Conference of State and Territorial Health Officers.

It would establish a Division of Control in the U.S.P.H.S., under the charge of a commissioned officer of the Service detailed by the Surgeon General. It would enable the Surgeon General to make studies, investigations, and demonstrations for more effective prevention, treatment, and control of the disease; to assist, through state health authorities, by grants, states, counties, health districts, and other political sub-divisions of states in establishing and maintaining adequate measures for prevention, treatment, and control, including construction, maintenance and operation, and the training of personnel for state and local health work; and to control the spread of tuberculosis in interstate travel. The Bill authorizes the appropriation of \$10,000,000 for the first year, and for thereafter "a sum sufficient to carry out the purposes" of the Act.

The Surgeon General, under the Bill's terms would make allotments to the states on the basis of population, the size of the tuberculosis problem, and financial need. Moneys would be expended by the states in accordance with plans presented by the health authority in each state and approved by the Surgeon General. Grants would be made on condition that state funds would be expended for the same general purpose in an amount to be determined in accordance with regulations prescribed by the Surgeon General, with the approval of the Federal Security Administrator.

The Bill has vigorous support. It is

in the hands of the House Committee on Interstate and Foreign Commerce, and the Senate Committee on Education and Labor. As this is written, hearings before the House Committee are expected to be held at once.

SUMMER POSTGRADUATE STUDY IN PUBLIC HEALTH NURSING

The American Journal of Public Health at the request of the National Nursing Council for War Service is glad to summarize courses which will be available during the coming summer for graduate public health nurses in the hope that health officers and others employing public health nurses may be encouraged to select nurses of outstanding abilities and promise and to make available to them courses of this kind.

Administration of Public Health Nursing, summer courses will be available at the University of Chicago, the University of Michigan, St. Louis University, and George Peabody College for Teachers, Nashville.

Health Education, Loyola University, University of Minnesota, George Peabody College for Teachers.

Industrial Nursing, Loyola University, University of Michigan, New York University, St. Johns University (Brooklyn), George Peabody College for Teachers.

Principles and Practice of Public Health Nursing, University of California at Los Angeles, Catholic University of America in Washington, Loyola University, University of Chicago, Indiana University, Simmons College, University of Michigan, University of Minnesota, St. Louis University, Seton Hall College in Newark, Columbia University, New York University, St. John's University, University of Buffalo, University of Syracuse, Western Reserve University, University of Oregon, Duquesne University in Pittsburgh, George Peabody College for

Teachers, Vanderbilt University, Incarnate Word College in San Antonio, University of Washington, Marquette University.

Public Health Nursing Supervision, Catholic University of America, University of Chicago, University of Minnesota, Columbia University, New York University, George Peabody College for Teachers, Incarnate Word College.

School Nursing, University of California, Catholic University of America, Loyola University, Simmons College, University of Michigan, University of Minnesota, Seton Hall College, Columbia University, New York University, University of Buffalo, University of Syracuse, Duquesne University, University of Pittsburgh, George Peabody College for Teachers.

Venereal Disease, University of California at Berkeley, University of California at Los Angeles, University of Michigan, University of Minnesota, St. Louis University, University of Texas.

The University of Minnesota will hold a summer workshop for concentrated short term study in Industrial Health and Community and School Health Education.

MARY SPALDING SCHOLARSHIP FUND

Simmons College announces a scholarship fund for the coming year for the graduate program in Public Health Nutrition. This fund has been contributed by friends of Mary Spalding, formerly Supervisor of Nutrition in the Massachusetts Department of Public Health, who prior to her recent retirement because of illness, made outstanding contributions to the field of public health nutrition.

Application blanks and further information regarding the program, which leads to the degree of Master of Science, may be secured from Dr. Elda Robb, Director of the School of Home Economics, Simmons College, The Fenway, Boston, Mass.

SYNTHESIS OF QUININE CLAIMED AS ACHIEVEMENT

The newspapers and radio on May 3 carried an announcement that the total synthesis of quinine had now been achieved after almost a hundred years of effort to build up this alkaloid.

Crediting Robert B. Woodward and William E. Doering, two 27 year old chemists at Harvard, with the discovery, the announcement was made by the Polaroid Corporation and released through censorship channels. According to this announcement, these workers within 14 months were able to synthesize a produce "which is an exact duplicate of natural quinine and which cannot be distinguished from it any way." It is said to be completely unlike atabrine and plasmochin.

According to the announcement, the process produces quinotoxine out of coal tar, but there is some doubt in the minds of the investigators whether their method can produce the drug in commercial quantities at the present time.

INSTITUTE OF HYGIENE OPENS IN HAVANA

The Institute of Hygiene, in Havana, Cuba, of which Dr. Moises Chediak is Director, was formally opened in new quarters on May 15. The American Public Health Association was represented by Dr. R. E. Dyer of the U. S. Public Health Service, Director of the National Institute of Health, who was a guest of the Cuban Government and who expressed greetings on behalf of the Association to the friends of the Institute.

Dr. Alberto Recio, the Minister of Health of Cuba, announces that the Institute which is now housed in the new buildings recently occupied by the headquarters of police, will have three divisions, namely, a division concerned with clinical diagnostic procedures, including parasitology, hematology, serol-

ogy, and bacteriology; a division concerned with sanitary, chemical, and physical examinations of water, sewage, swimming pools, food, and drugs; and a division for the manufacture of vaccines, plasma, sera, etc., to supply the public hospitals and dispensaries of Cuba. Close relationships will be developed with the Hospital for Infectious Diseases.

The Institute will have a staff of 150 persons, including 10 physicians and at least one sanitary engineer. It is under the direction of a board of 7 trustees appointed by the President. According to Dr. Chediak, the Institute, which until two years ago was a part of the Finlay Institute, will carry on the above functions, leaving to the Finlay Institute the functions of teaching and research.

FLORENCE PHENIX JOINS CHILDREN'S BUREAU

The Children's Bureau announces the appointment of Florence Phenix to the Nursing Unit, Division of Health Services of the Children's Bureau, as special consultant nurse in Crippled Children's Services. Miss Phenix was associated for a number of years with the Crippled Children's Division of the Bureau for Handicapped Children, Wisconsin State Department of Public Instruction, and more recently with the New York City Department of Health.

In her new position she will act as special consultant to state agencies in orthopedic nursing and physical therapy as arranged by the regional offices of the Division of Health Services of the Children's Bureau.

FELLOWSHIPS IN HEALTH EDUCATION OFFERED BY THE U. S. PUBLIC HEALTH SERVICE

Fellowships for graduate study and experience in health education will be offered to qualified women this fall by the U. S. Public Health Service through

funds made available by the W. K. Kellogg Foundation. They will lead to a Master of Science degree in Public Health.

The fellowships will provide 12 months' training in public health education with 9 months devoted to academic work in public health and public health education, and 3 months to supervised field experience. A stipend of \$100 a month for 12 months, full tuition and travel for field experience is included.

Only women will be considered for fellowships at this time. Women who are citizens of the United States between the ages of 19 and 40 years, inclusive, who possess a Bachelor of Science degree, or its equivalent, from a recognized college or university may apply.

The announcement of the fellowships from the U. S. Public Health Service states that

... the demand for qualified health educators in the past few years has increased to such an extent that at present there are not enough trained personnel to meet existing openings. Expanding fields are opening to the health educator through the local, state, and federal health departments, schools, and voluntary agency programs of community and school health education. Leading public health authorities have recommended that a health educator be added to every local health department in the country, and the need for health education personnel abroad is foreseen.

Forms for application for fellowships may be obtained from the Surgeon General, U. S. Public Health Service, Washington 14, D. C. Applications must be accompanied by a transcript of college credits and a small photograph and must be in the office of the Surgeon General not later than August 1, 1944.

DR. CUMMING ELECTED PRESIDENT OF THE PAN AMERICAN UNION

Dr. Hugh S. Cumming, Director of the Pan American Sanitary Bureau, has

been elected President of the Pan American Conference of National Directors of Health, at the Fifth Conference held in Washington in April. Other officers elected are: Dr. Aristides A. Moll, Secretary General; Dr. Manuel Martinez Baez of Mexico; Dr. Eugenio Suarez of Chile; Dr. Cesar Gordillo Zuleta of Peru; and Dr. Leopoldo Izquieta Perez of Ecuador, Vice-Presidents.

NEW YORK STATE HEALTH DEPARTMENT WINS NATIONAL SAFETY AWARD

"Four Point Safety Home," the latest motion picture film of the New York State Health Department has received the award of the Film Safety Awards Committee of the National Safety Council for "the best home safety nontheatrical film" of 1943. The award was presented on April 12 at a meeting of the Western New York Safety Conference in Buffalo. The award, a model "Oscar," was accepted for the department by Dr. Paul B. Brooks, Deputy Commissioner, on behalf of Dr. Edward S. Godfrey, Jr., Commissioner. Also present at the ceremony were Burt R. Rickards, Director of the department's Division of Public Health Education, and Thomas C. Stowell, Assistant Director, under whose supervision the film was produced.

SUPREME COURT OF CALIFORNIA UPHOLDS DECISION IN FAVOR OF HEALTH DEPARTMENT

The outcome of a case in California involving the Natural Milk Producers Association and the City and County of San Francisco is of interest to health officials. The case has been in process for more than two years. The Supreme Court of California upheld the San Francisco ordinance requiring the pasteurization of all milk sold in the City and County of San Francisco on the grounds that such was not

contrary to the sections of the Agricultural Code but merely imposed additional restrictions and higher standards than those required by the state law. Following that decision the plaintiff took the case to the Supreme Court of the United States, which court determined that there were no federal questions involved and hence referred the case back to the Supreme Court of California for such further proceedings as the latter might deem appropriate. The Supreme Court of the state reaffirmed and adopted its original opinion.

This information comes from Dr. J. C. Geiger, Director of Public Health, City and County of San Francisco.

HENRY STREET SERVICE APPOINTS NEW DIRECTOR

The Board of Directors of the Henry Street Visiting Nurse Service have announced the appointment of Marian G. Randall, R.N., as Director effective June 1. Elizabeth C. Phillips, R.N., who has been Acting Director, resumes her former position as Assistant Director.

Miss Randall served as Assistant Director of the Henry Street Visiting Nurse Service in charge of records and statistics, from 1938 to 1941, when she left to take a wartime position as principal nursing consultant in the U. S. Public Health Service, assigned to the Medical Division of the U. S. Office of Civilian Defense, Washington, D. C. Since completion of this assignment, she has been making a study of prepayment plans for nursing service for the Associated Hospital Service of New York.

She is Secretary of the Public Health Nursing Section of the American Public Health Association.

REPORT ON FILM EQUIPMENT SURVEY

Film planning can be done much more effectively when agencies which

make films have at least a broad picture of the type of film-showing equipment available among the groups they wish to reach. The value of such information has been demonstrated by the recent Department of Commerce studies of visual aid equipment on hand in elementary and high schools. Figures on equipment available in another group—this time community agencies—are now released as the result of a survey made by the Metropolitan Life Insurance Company.

The Motion Picture Bureau of the company's Welfare Division, under the direction of Dr. Donald B. Armstrong, sent a questionnaire to social, health, and safety agencies all over the country to find out how many agencies had access to or owned equipment for showing films. These agencies were also asked to indicate what type of equipment they had—sound or silent, 35mm. or 16 mm., film strip or glass slide projectors. The organizations surveyed cover a wide range, including among others urban and rural health departments, various nursing organizations, family welfare associations, boys' clubs, schools of medicine, nursing, and social work, safety councils, and tuberculosis associations.

Replies came from more than half of the 5,000 organizations that received the questionnaire. More agencies report having 16mm. projectors, both sound and silent, than any other equipment. Schools of medicine and nursing own most of the glass slide projectors. As might be expected, boys' clubs favored sound equipment 2 to 1.

An analysis of the returns shows other facts which may be of interest to social and health agencies. Full details of the results of this survey may be had for the asking by any official or voluntary social, health, or safety agency that may find them useful. The Metropolitan Motion Picture Bureau

will furnish information regarding the entire survey, or as broken down by localities or types of organizations in accordance with the request.

In addition to this information, the Motion Picture Bureau has a library of catalogs of motion pictures and film strips available through universities, museums, safety councils, federal and state government departments, industries, etc., covering many subjects. The bureau will suggest sources of films on particular subjects to agencies requesting them. For any information on this survey of film equipment, the company's own films, or films available through other sources, write to: Dr. D. B. Armstrong, Third Vice-President, Welfare Division, Metropolitan Life Insurance Company, 1 Madison Avenue, New York 10, N. Y.

PERSONALS

Central States

JOSEPH HOWARD BEARD, JR., M.D.,* Urbana, Ill., has been lent by the U. S. Public Health Service to become Health Officer of Wilkinson County, Woodville, Miss., to succeed ROBERT M. WINGARD, M.D.†

DANIEL W. MEAD,* who is Emeritus Professor of Hydraulic and Sanitary Engineering at the University of Wisconsin, has been elected an honorary member of the Canadian Institute of Engineers. Mr. Mead became a member of the American Public Health Association in 1892 and a Fellow in 1922 and is the recipient of the 40 year certificate of membership.

F. A. MUSACCHIO, M.D., M.S.P.H.,† formerly Director of the St. Joseph County (Michigan) Health Department, has accepted the directorship

of the Laredo-Webb County Health Unit, Laredo, Tex.

EMILY L. RIPKA-HAUTA, M.D., M.P.H.,† Roscommon, Mich., has been appointed Health Officer of Midland County to succeed RALPH R. SACHS, M.D., M.P.H.†

Eastern States

THOMAS R. CAMP,* Boston, Mass., has resigned from the faculty of the Massachusetts Institute of Technology, where for 15 years he has been in charge of sanitary engineering, to engage in full-time practice as a consulting engineer with offices in Boston. He will specialize in water works, sewage works, municipal and industrial waters, stream sanitation, and flood control. Mr. Camp is a graduate of Texas A. & M. College and received a Master's degree from M.I.T. in 1925.

KATHARINE FAVILLE, R.N.,* recently Director of the Henry Street Visiting Nurse Service, New York, N. Y., has accepted a position as Director of the Department of Nursing at Wayne University, Detroit, Mich. Miss Faville will be in charge of the 4 year basic program in nursing education as well as the program of graduate study for public health nurses and instructors in schools of nursing.

Southern States

HUGH S. CUMMING, M.D.,* Surgeon General (R), U. S. Public Health Service, was elected President at the Fifth Pan American Conference of National Directors of Health held in Washington, D. C., April 22. Dr. Cumming is Director of the Sanitary Bureau of the Pan American Union.

E. V. MCCOLLUM,* Professor of Biochemistry at the School of Hygiene and Public Health, Johns Hopkins

* Fellow A.P.H.A.

† Member A.P.H.A.

University, Baltimore, Md., has been elected a foreign member of the Swedish Academy of Sciences. Dr. McCollum has also been announced as the first recipient of the Borden Nutrition Award given by the American Institute of Nutrition "in recognition of his long years of pioneering research in nutrition. His contributions to our knowledge of the Vitamin content of milk and of the high nutritive value of protective foods, have served as foundation stones for improving through food the nutrition and health of the human race."

THOMAS F. MCGOUGH, JR., M.D.,† Health Officer of Pulaski-Wythe Health District, Pulaski, Va., resigned effective January 16 to enter military service.

ROE E. REMINGTON, PH.D.,* has resigned as Professor of Nutrition and Director of the Food Research Laboratory of the Medical College of the State of South Carolina, a post which he has held since 1928, as reported by *Science*.

THOMAS SCARLETT, M.D.,† Health Officer of Harrisonburg, Va., resigned, effective February 12, to enter military service

HAROLD W. SEFF, M.D., of Chattanooga, Tenn., has accepted the position of Health Commissioner of the Delaware City and County Board of Health, Delaware, Ohio.

DANIEL C. STEELSMITH, M.D., Health Officer of Halifax-Pittsylvania Health District, South Boston, Va., has resigned effective April 1.

BEN F. WYMAN, M.D.,† has been appointed as State Health Officer effective May 1, according to an announcement made by The Honorable Olin D. Johnston, Governor of South Carolina. Dr. Wyman has been Director of Rural Sanitation and County Health Work in the same department since 1926.

Western States

CHARLES R. BLAKE, JR., B.A.,† on account of ill health, has resigned as Health Officer of Richmond, Calif.

EDWIN N. HESBACHER, M.D.,† Assistant Surgeon, U. S. Public Health Service, has been appointed Director of Venereal Disease Control of the Seattle Health Department, Seattle, Wash. He succeeds BURTON L. ZINNAMON, M.D., who has been transferred to Oakland, Calif.

EMIL E. PALMQUIST, M.D.,† M.S.P.H., who for several years has been Health Officer of the Olympic Health District, Washington, including Clallam and Jefferson Counties, has resigned to become Health Officer of the King County Department of Health, Washington, including the county area outside of Seattle.

MARTHA SHAMBERGER, M.P.H.,† has been appointed Health Education Representative with the Washington State Department of Health, Seattle, Wash. Miss Shamberger was recently associated with the Oregon Tuberculosis Association, Portland, Ore.

Foreign

WILLIAM H. ADOLPH, PH.D., has been appointed acting professor of chemistry and nutrition at the School of Nutrition of Cornell University, Ithaca, N. Y. Dr. Adolph for several years has been Chairman of the Department of Chemistry at Yenching University, Peking, China.

Deaths

CARLOS EDUARDO FINLAY SHINE, M.D.,* former Secretary of Health and Professor of Medicine of the University of Havana, Havana, Cuba, died March 11 at the age of 76. The son of Carlos J. Finlay, pioneer

International Vital Statistics of the Future*

FORREST E. LINDER, PH.D.

*Assistant Chief, Division of Vital Statistics, Bureau of the Census,
Washington, D. C.*

PERHAPS most of the statistical analysts here can recall their first experience in making a comparative vital statistics study for various countries of the world. After a few days of hard work in the library it was soon discovered that it is very difficult if not impossible to make satisfactory world-wide vital statistics studies. Data for even some of the large countries are not available; there is a wide variety of methods of compilation and classification; and there exist no general standards for completeness and accuracy.

Confronted with such a situation, the analyst is likely to give some thought to the problems of collecting and compiling vital statistics so that international studies would be possible. Obviously, progress toward the desirable goal of world-comparable vital statistics depends upon a clarification of the responsibilities and interests of the numerous governmental units which contribute to

the production of those statistics. In the United States, the city, the county, the state, and the federal government each has an essential and a distinctive responsibility in the United States vital statistics collecting organization; and, in turn, each has its own distinctive uses and needs for the records and data it has helped to collect. A similar pattern will be found in other countries. And beyond the scope of national government, those official and private organizations concerned with international problems of health or health statistics have a contribution to make to, and a real interest in, hemisphere or world vital statistics.

The fact that each unit in the governmental hierarchy, from the smallest town to the most global world organization, has an interest in vital statistics is no indication that these interests are the same. The smaller units of government need and can produce intensive and detailed analyses of local data. The work of each larger governmental unit becomes successively more extensive and correspondingly less intensive. No

* Presented before the Vital Statistics Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 13, 1943.

state vital statistics office could hope to duplicate the type of intensive demographic studies which can be made in a progressive city office. In such a local office, data can be tabulated on a tract basis and studied in relation to other tract data with a direct knowledge of pertinent local conditions. The data can be tabulated week by week or day by day, and if necessary, cases can be individually listed for exhaustive special investigation. The state office has the opportunity for more extensive analyses based on consolidated data for the whole state or upon the comparison of areas within the state. But to the degree that the state totals are a consolidation of heterogeneous data or that the comparisons involve noncomparable areas, the possibility of detailed study is lost. Similarly the work of our national agencies, based on interstate comparisons or on consolidated data for 48 states, loses in detail and validity as much as it gains in scope and generality. In the international field the extensivity of interest is so great and the data under consideration are so heterogeneous that it is difficult to make even the vaguest conclusion or the most general comparison.

Although the contributions and requirements of each unit in the vital statistics organization are different, they are by no means independent. The vital statistician for any city can analyze his material on an *internal* basis, taking into consideration differences and facts within his area. However, much would be added to the value of his analysis if it were also studied on an *external* basis by making comparisons between his city and others. The vital statistics for the whole United States are of more value when viewed against a background of international vital statistics, and if there are men on Mars, I assume that the global statisticians will some day be making interplanetary comparisons.

The interest of the statistician for one area in the vital statistics of other areas is not due to the need of data for external comparisons only. A factor of greater importance is the interdependence of the various areas of the country with regard to health conditions. Health conditions in your own city, state, or country which result in unfavorable mortality would be of importance to you. Similar health conditions in an adjacent area might be of equal interest if there was a danger of them spreading. A health official in Maine might well be concerned with the vital statistics of a potential epidemic in California. In these days of rapid world transportation, the United States must become more and more concerned with the vital statistics of the other nations of the globe with whom we maintain social and economic relations. Like wars, epidemics have no respect for political boundaries.

This dual dependence of the medical statistician in one area upon the data produced by a statistician in another area is a strong unifying force which has advanced vital statistics further along the road to world comparability than any other statistical field. In effect, it means that the statistician in any unit of the system has a real and legitimate interest in the methods, procedures, and programs of every other unit. Each unit within a state has an interest in the work of the state vital statistics office because the activities of that office affect the type of external statistics which a city or county may be able to get. Each state statistician has a legitimate concern and responsibility with the problems of national collection because the actions or recommendations of a national agency may facilitate or hinder the essential external studies made by the various states. Each national government has a responsibility to partake in and contribute to those international activities

which have world comparability as their ultimate goal.

When every governmental unit contributes to and in turn is dependent upon a vital statistics system, is it too much to hope that ultimately we shall have an integrated and coördinated world vital statistics system?—and that then, the elusive goal of “comparability” will become somewhat more of a reality?

Such a concept of a world vital statistics system carries with it no necessary implication of a super world government. More, perhaps, can be attained by the coöperative efforts of the independent countries working together with some international coördinating agency. Much more can be accomplished by such methods than is ordinarily realized. Take a single example from our own voluntary system of federal-state vital statistics. Make this simple test: On a table, spread out copies of the death certificates in use by each of the independent state and city death registration units. Then, spread out the records for some other state activity—such as marriage certificates, or licenses for automobile drivers. Among the death certificates you will note a surprisingly high degree of uniformity and comparability. Among the other records, you will almost certainly find a great variation.

The state-to-state uniformity of the death records is the result of no mandatory national law but is rather one of the many results of 40 years of continuous coöperative effort between national, state, and city officials—each realizing his responsibility in and his need for a coördinated organization.

Already substantial progress has been made in the field of international comparability of vital statistics. The almost universal use of the *International List of Causes of Death* represents an achievement that has no counterpart in any other statistical field. Widespread

recognition of the need for better international vital statistics is opening the door for further progress. The Eighth American Scientific Congress, the Fourth Pan American Conference of National Directors of Health, the XI Pan American Sanitary Conference, the First Pan American Conference on Social Security are some of the inter-American conferences of recent years which have adopted specific resolutions and recommendations calling for an improvement in national and international vital statistics. In the Western Hemisphere several inter-American agencies are taking active steps to assist in coördinating and stimulating efforts for the development of vital statistics among the American Republics. The Pan American Sanitary Bureau and the Inter American Statistical Institute are both actively interested in improving sources and comparability of demographic data.

The inter-American program of the Vital Statistics Division of the Bureau of the Census can be considered as one small contribution to the solution of the problems of international vital statistics. This program has four inter-related parts. The first part involves the lending of technical consultants to other American Republics that request such assistance for the reorganization or improvement of their vital statistics methods. Under this program one Census Bureau field consultant is working in the Caribbean Area and another is in Central America. Several additional projects are now being formulated for South America.

A second part of the program involves offering fellowships to South American vital statisticians who wish to study in this country. This part of the program is not yet under way, but it will probably be started on a small scale this year. In addition to its own fellowship program, the Bureau is coöperating with other governmental

and non-governmental agencies by offering some training in the administrative aspects of vital statistics to students brought to the United States by those other agencies.

The third part of the Census Bureau program is a systematic compilation from published sources of vital statistics data for each of the American Republics. Such compilations have been completed for 3 countries and during the course of the next 12 months, demographic compilations will be undertaken for 17 others. These compilations will ultimately form the foundation for a comprehensive study and analysis of the demographic and public health problems of the Western Hemisphere.

The fourth aspect of the Census Bureau program is an effort to improve and standardize vital statistics methods by the preparation and distribution of those "tools" which a vital statistician needs in his work. An elementary manual on vital statistics has been prepared, translated into Spanish, and published by the Ministerio de Salud Pública of the Republic of Uruguay. This *Manual de Estadística Vital* has been reprinted and given wide distribution by the Census Bureau. It is also being reprinted in the official statistical journal of one South American country and is being translated into Portuguese for publication in the official statistical journal of Brazil. In order to provide a tool for the conversion of technical matter from one

language to another, the Bureau has prepared and distributed a *Vocabulario Bio-estadístico* which gives Spanish-English equivalents of some 1,600 common terms used in vital statistics. Plans are also being made for the preparation of a Spanish edition of the index of the *International List of Causes of Death* and the conversion of other "work tools" of the statistician to a bilingual or multilingual basis.

There is no mistaken optimism that this program will quickly solve the problems of inter-American comparability and that we may now expectantly look forward to the immediate availability of adequate medical statistics for the American Republics. The goals are difficult and far from attainment.

There is little agreement of opinion even within our own country regarding the ideal goals of a vital statistics system and the proper methods of attaining those goals. Before much can be accomplished in the international field these objectives must be more clearly formulated and the prerequisites and methods for the system must be more adequately explored. In addition, some fundamental problems of organization must be solved. The most optimistic sign is the general recognition of the fact that although the needs of different units of the statistical system are distinct, their interests are interdependent. Substantial progress from now on will require the coöperative work of local, state, national, and international vital statisticians.

Army Field Water Supply Developments*

HAYSE H. BLACK, C.E.

*Captain, Corps of Engineers, Chief, Water Supply Equipment Branch,
The Engineer Board, Fort Belvoir, Va,*

THERE are few items of Army supply more important than potable water. Production of potable water in adequate quantities for field troops is just one of the many and varied military assignments of the Corps of Engineers. Global mechanized warfare has introduced innumerable water supply and water treatment problems heretofore not conceived. The purpose of this paper is to cite some of the more important water supply developments resulting from American participation in World War II.

Some conception of the problems confronting the Corps of Engineers may be realized from consideration of the fact that provision must be made for supplying potable water to the individual soldier, whether he be a part of a small detachment on an isolated island or a member of an organization making up a field army. The water supply problems of task forces are frequently more complicated than those presented by larger troop movements. The widespread dispersion of American forces has recently been discussed by General George C. Marshall, Chief of Staff of the U. S. Army, in his biennial report to the Secretary of War, where he reported that American troops were

stationed in 51 different places around the world. This is indicative of the potential water supply problems.

The field army will be forced to utilize such sources as sea water, grossly polluted streams, and brackish well waters in addition to more acceptable ones. These conditions make it imperative that equipment and processes be available to permit the accomplishment of military missions, and Army water supply processes and equipment are designed to meet the highly variable field conditions anticipated.

ORGANIZATION, FACILITIES AND EQUIPMENT

The Engineer Board is the development agency for the Corps of Engineers, operating under the general direction of the Engineering Division, Office, Chief of Engineers, U. S. Army. The Water Supply Branch of the Engineer Board is charged with the conduct of research and development pertaining to water supply for the Army.

The main offices of the Engineer Board are located at Fort Belvoir, Virginia, where administrative functions, research, and a substantial portion of the development are conducted. Field parties are established in areas where the environment is conducive to special testing. The Water Supply Branch maintains two extensive field sections

* Presented before the Engineering Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 13, 1943.

FIGURE 1—Water Supply Branch Laboratory, Equipment Test Room

for testing and development of water supply equipment. Well equipped shops and field offices are provided for these sections for maintaining and servicing units under test.

The Water Supply Branch Laboratory, recently completed, was designed for its special tasks. This modern laboratory is equipped for chemical and bacteriological analytical work, water purification and hydraulic studies, and physical testing of water supply mechanical equipment. A spectrograph, complete with comparator-densitometer, is provided for qualitative and quantitative chemical analyses. Abundant space is available for pilot plant and full scale studies. Equipment being developed is subjected to full scale testing prior to being recommended to the Chief of Engineers for adoption. A view of a portion of the laboratory is shown in Figure 1.

WATER PURIFICATION

Recent desert warfare focused attention on water distribution when its scarcity necessitated transporting it long distances. This is an abnormal military function and every effort is made to reduce the length of haul for water to an absolute minimum. This means that in those areas where water is available, it is expected that such treatment as is necessary will be employed to produce a satisfactory and safe drinking water. Satisfactory accomplishment of water purification under all field conditions is a foregone conclusion to the American soldier who in civilian life was accustomed to uninterrupted water service.

Although basic principles of water purification are well established, the adaptation of them to field Army requirements presents many problems which do not normally concern water

works men. Full cognizance is taken of the fact that proven design factors and operation procedures for water purification in fixed installations may be relied upon to produce a safe treated water. These same principles, however, when applied to portable equipment, frequently introduce complications. It will be appreciated that the multiplicity of Army field water supply problems invite and occasionally result in deviations from standard water works practice.

Current standard mobile and portable water purification equipment tends toward excessive filtration rates and inadequate pretreatment of the water to be filtered. This is a natural consequence of an attempt to produce the maximum amount of potable water with a minimum of equipment and supplies. The efficiency of this field equipment has been studied in collaboration with the National Institute of Health, U. S. Public Health Service, in order to determine its limitations and to establish optimum operating procedures. Improved results are attainable through reduced filtration rates and provisions for intermediate coagulation and sedimentation. Although these modifications result in an improved filtered water, treatment with germicidal agents continues to be an extremely important step in producing a potable water.

Novel water problems appear in foreign areas. Schistosomiasis, which is virtually unknown in the United States, is endemic in many tropical and subtropical countries. The disease is caused by cercariae, which enter the body through the skin and thus become a bathing as well as a drinking water problem. Due to the resistance of the cercariae to chlorine and their ability to penetrate sand filters, it becomes necessary to resort to longer storage, higher chlorine residuals or improved filtration when these organisms are

present in the raw water. Present practice favors chlorine rather than chloramine as a cercaricide but their relative efficiency is still in doubt and is to be investigated.

Manufacture and distribution of water purification chemicals in wartime present new and unusual problems. Demand for chemicals frequently prohibits normal refinement in the finished product, necessitating tolerance of impurities not commonly accepted. New processes have been developed for manufacture of coagulants, giving products which will contribute to post-war water treatment. As a result of these developments, satisfactory water purification chemicals have been made available in quantities to satisfy Army requirements.

Studies of calcium hypochlorite have shown a definite correlation between moisture content and container corrosion. High moisture (10 to 20 per cent) calcium hypochlorite has been found to cause failure of metal containers in one year's storage. An interesting observation in this study has been the stability of this product. Calcium hypochlorite, in corroded containers allowing exposure to the atmosphere, still retains approximately 75 per cent of its original available chlorine content. However, there is ample justification for specifying a low moisture product; that is 2 per cent moisture or less.

Facilities have been made available for sterilization of large quantities of either filtered or untreated water. Commercial equipment has been incorporated into a protective framework, along with solution reservoir, water meter, water line connection and diffuser tube. The apparatus applies sterilizing agent in direct proportion to the main line flow, being operated by water under pressure from the supply. This equipment is flexible, and by improvising it can be made to

treat water over a wide flow range. This particular equipment is well adapted for treatment of municipal water supplies in occupied areas.

DIATOMACEOUS SILICA FILTRATION

Research has been directed toward effective, lightweight, portable water filtration equipment. Diatomaceous silica has been intensively investigated by the Engineer Board during the past six months as a possible filter medium to replace sand now being used in Army water filtration equipment. The excellent results obtained from these studies indicate that diatomaceous silica filtration is superior to sand filtration for portable water purification equipment.

Inasmuch as diatomaceous silica is a relatively new medium for water filtration, the following description should be helpful in understanding this application. Diatomaceous silica is the refined product obtained from sedimentary diatomite, the deposits of fossil valves or shells of diatoms. The diatom, a single-celled marine plant, which is related to algae, secretes a siliceous frustule consisting of two valves which inclose the entire shell. Deposits of diatomaceous silica (the unrefined product is commonly known as diatomaceous earth or Kieselguhr) were formed in shallow water during the Miocene period and subsequently raised above sea level to form deposits along the Pacific coast in this country. Diatomite is mined in open pits, crushed, classified, and treated to produce a variety of commercial filter-aids that have been used for a number of years by the process industries in the clarification of sugars, chemicals, oils, fruit juices, varnish, and other liquids. The principal component parts of the diatomaceous silica filter are the diatomaceous silica itself and a rigid support, hereafter referred to as filter membrane, upon which the filter medium forms as a porous filter cake. Ex-

tensive tests have been conducted with different types of filter membranes such as those constructed of aluminum oxide, carbon, and Monel wire. Rigid, porous filter tubes made of aluminum oxide or carbon and wire-wound fluted cores appear to be superior to other types of filter membranes tested.

The diatomite filter is placed in operation by applying an initial layer of filter-aid known as "precoat," which is formed by pumping a suspension of diatomaceous silica (0.1 to 0.15 lb. per sq. ft. of filter surface) through the filter membrane at the rate of 2 to 4 gal. per sq. ft. per minute. The water containing this suspension is circulated until the material is deposited and until the filtered water is free from turbidity. Enough water, preferably filtered, to fill the system is used in mixing the diatomaceous silica suspension. Flow through the filter membrane is inversely proportional to the resistance, causing a coat of uniform thickness to form.

Inhibition of an impervious "schmutzdecke" is accomplished by continuous addition of the diatomaceous silica to the water being filtered. The diatomaceous silica added during the filter run is termed "body-feed." The body-feed combines with the suspended materials to form a cake that remains porous, permitting extended filter runs at reasonable pressures. The amount of body-feed required varies with the amount and nature of the suspended matter in the water. Tests indicate that the ratio of filter-aid to turbidity by weight is approximately 1.25 to 1 for inorganic silt and 3 to 1 for organic slimes. Body-feeding has been accomplished by utilizing pressure differentials such as that produced by pump suction or a Venturi throat, but it is believed that positive and proportional mechanical feeding is preferable.

The filter cake is readily removed by reversing the flow through the filter membrane. Normally, the filter is

allowed to drain, after which approximately 10 gal. of filtered water per sq. ft. of filter surface is pumped in reverse through the filter membrane at a rate of 7 to 10 gal. per sq. ft. per minute. The filter cake may be easily removed by air in lieu of backwash water.

Tests conducted in collaboration with the National Institute of Health, U. S. Public Health Service, have shown that diatomaceous silica filtration will effect complete removal of the cysts of *Endamoeba histolytica*. NRS strain cysts were used in this research. This type filtration has likewise been proved to be highly effective in removal of bacteria. Rapid sand filtration, at rates in excess of the accepted standard, was proved ineffective in removal of the NRS strain cysts of *Endamoeba histolytica*. Special tests were conducted with intermittent flow and vibration of the diatomaceous silica filter unit to simulate adverse operating field conditions with the result that no cysts appeared in the filtered water from correctly designed units. The results of these tests demonstrated that diatomaceous silica will accomplish complete removal of *Endamoeba histolytica* cysts irrespective of the nature of the raw water or the concentration of the cysts at flow rates as high as 7 gal. per sq. ft. per minute.

Removal of turbidity with diatomaceous silica filtration is essentially complete. Suspensions of extremely fine clay or algae have been readily filtered, producing a filtered water that gives no tyndall effect when a strong beam of light is passed through the water in a darkened room. This corresponds to a turbidity of absolute zero on any turbidimeter in use, a turbidity of 1.0 p.p.m. on the St. Louis turbidimeter, giving a solid cone of reflection in the light beam. Tests indicate that the removal of microorganisms may be highly effective.

Since a close correlation between the amount of turbidity and the number of microorganisms was found in all tests, water producing no tyndall effect may approach sterility. Activated carbon introduced with body-feed has been used to remove tastes, odors, and color.

The quality of the filtrate appears, within limits, to be independent of the flow rate for a given filter-aid. This characteristic of diatomaceous silica filtration permits relatively high filtration rates as compared with sand filtration. The clarity of the filtrate produced with proper grades of filter-aid is striking. Turbidities ranging from 0 to 0.3 p.p.m. on the St. Louis turbidimeter or tyndall effect instruments have been consistently attained. Particle size for diatomaceous silica ranges from 0.5 to 12.0 microns, whereas filter sand may vary from 300 to 600 μ . Considering the particle size, the mechanical straining action may be expected to be much more effective with diatomaceous silica than with sand and with relatively thin layers of this material. Furthermore, the indented diatom valves may be expected to perform more efficiently than relatively smooth grains of sand in removing particles by adhesion. Tests have shown that the use of minute amounts of coagulants with filter-aid will produce a filtrate that gives no tyndall effect with a strong beam of light.

Average flow rates have been steadily increased as a result of this research from approximately 2.5 to 6.0 gal. per sq. ft. per minute when filtering water containing 200 p.p.m. of alluvial clay. Higher flow rates are in prospect with treated filter-aids and using higher capacity, higher pressure pumps. The military value of diatomaceous silica, as a filter medium, becomes most apparent when it is realized that the precoat requires only 0.1 to 0.15 lb. of material per sq. ft., whereas the conventional sand filter requires approximately

200 lb. of sand to give 1 sq. ft. of filter surface.

Since effective coagulation and sedimentation are not required with diatomaceous silica filtration, operation becomes independent of chemical constituents in the raw water when treated filter-aids are used. Filtration operations are accordingly simplified. Water of high turbidities may be filtered at high rates by increasing body-feed, producing the same quality of filtered water as obtained from low turbidity sources.

Advantages of diatomaceous silica over other recognized filter media for water may be summarized as follows:

1. Higher output per unit weight
2. Improved quality of filtered water
3. Simplified operation

Cognizance is taken of the fact that diatomaceous silica filtration of water must prove its worth to the water works profession. It is further realized that there are still many unknowns in the study of diatomaceous silica filtration. Results of studies conducted by the Engineer Board indicate that diatomaceous silica approaches an ideal filtering medium for use in portable water filtration equipment and that its potentialities should attract the interest of research workers in the water works profession.

GROUND WATER DEVELOPMENT

There are large areas in the world likely to be occupied by American troops where dependence must be placed upon ground water. This situation has necessitated providing equipment to locate and produce ground water under a great variety of conditions. In undertaking this work, cognizance has been taken of the fact that machines and equipment, used commercially in developing ground water supplies, have evolved through years of experience of dependable manufacturers with the benefit of advice from

skilled and critical well drillers. It has been possible for the most part to adapt available commercial equipment to specific military purposes.

A primary consideration in the development of well drilling equipment for military work is the decision relative to the proper accessory equipment and spare parts to accompany each machine going into the theater of operations. The spare parts problem is alleviated somewhat by standardization of equipment. Every effort is made to

FIGURE 2—Lightweight Rotary Well Drilling Rig

control design so as to reduce maintenance to an absolute minimum. Army requirements place special emphasis on such features as flexibility, mobility, and maneuverability of equipment. Due consideration is given to such factors as weight and volume of equipment and supplies. Speed of drilling and the ability to produce water in a minimum of time are of paramount importance.

In the past, there has been considerable controversy over the relative merits of the rotary and the cable tool methods for drilling water wells. There are certain geologic conditions which dictate cable tool drilling and there are other conditions when the rotary drill must be used. Cable tools are unsatisfactory and at times inoperative in soft, loose, unconsolidated caving formations; such as dune sand, quicksand, unconsolidated river gravels and for small diameter deep holes in unconsolidated material. Rotary machines are unsatisfactory and at times inoperative in cavernous or extremely porous "lost circulation" zones. These limitations make it mandatory that a well rounded water well drilling organization have available both types of equipment and trained personnel capable of handling each type.

Development work with well drilling equipment has resulted in a lightweight rotary drill. The objective of this design has been to provide highly flexible equipment possessing maximum maneuverability. This equipment is designed for exploratory drilling and demolition work as well as prospecting for water wells. A hydraulically-actuated diaphragm mud pump is an interesting component of this rotary drill. The accompanying picture, Figure 2, illustrates the drill proper.

A considerable amount of work has been done in the development of hi-lift pumping equipment for small diameter water wells. The objective of this

work has been to develop dependable pumping equipment which will give maximum production from small diameter water wells. Due to limitations of weight and transportation, it is impractical to drill normal industrial type, large diameter deep holes in field military operations. Design of deep well pumping equipment is consistent with capacities provided in the Army well drilling rigs and suitable for use in water wells drilled in world-wide military operations.

The development work pertaining to ground water has resulted in equipment which should prove valuable to the industry following the war. Data have been accumulated which should be of use in other phases of Corps of Engineers operations. Reference is made to application in pumping of mud fluids, slushes, cement grout, chemicals, and fluids containing suspended solids.

WATER DISTILLATION

The Engineer Board, in collaboration with interested manufacturers, has performed pioneering research in development of portable sea water distillation equipment. This development work was initiated late in 1940. Phenomenal progress has been made during this period and equipment is now available which gives economies heretofore considered fantastic.

Distillation equipment is used to produce potable water for troops, or water low in total solids for other military purposes, from sea water, brackish water, and other waters containing excessive amounts of dissolved solids. This development has resulted in portable, compact, self-contained equipment complete with power plant, source of heat, pumps, accessories, and controls. Design of this equipment has taken into consideration necessary ruggedness to withstand military handling and simplicity to assure satisfactory operation by soldier personnel.

Single effect, multiple effect, and thermocompression distillation equipment have been developed. This equipment may be classified into two groups according to the source of heat for operation:

1. Oil-fired in which heat is supplied to a steam generator or boiler by burning liquid fuel for single and multiple effect equipment.
2. Compression type in which heat for evaporating water is supplied from compressed steam.

Initially, development was focused on single and multiple effect direct oil-fired distillation equipment. Through a progressive development program, economies were realized up to 36 lb. of distillate per lb. of fuel consumed. Multiple effect distillation equipment utilizes latent heat of vaporization of steam generated in the first effect evaporator to evaporate additional water in subsequent effects, thereby increasing economy of the unit. Direct oil-fired stills possess certain inherent advantages in that they permit heating of water and production of steam for other military field uses.

Ferrous metals are utilized where possible in lieu of materials more resistant to corrosion by sea water. Extensive service of such equipment has shown that deterioration is not a serious factor and that the direct-fired equipment of essentially ferrous construction is satisfactory for military field use.

The objective in continued development of distillation equipment has been to increase economy without sacrificing weight, ruggedness, and simplicity. Compression type distillation equipment most nearly approaches this objective. The successful development of portable compression type distillation equipment constitutes an outstanding advancement in the field of distillation. The initial source of power and heat for compression type distillation is a water-cooled engine. The steam compression cycle is started by passing steam from the engine water cooler to the steam dome of the evaporator. Raw water which has been preheated in a highly efficient heat exchange system is passed into an

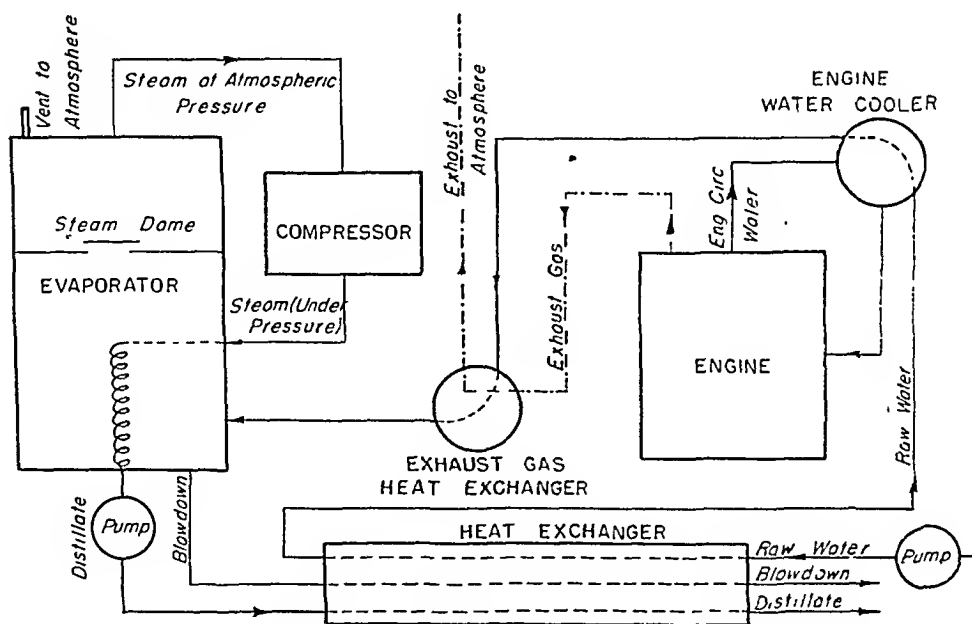

FIGURE 3—Flow Diagram of a Thermocompression Type Distillation Unit

FIGURE 4—Thermocompression Water Distillation Unit

evaporator where it is converted into steam. This steam is compressed, thereby causing temperature rise. The compressed steam is returned to the condenser section of the evaporator, which surrounds the boiling section, where it is condensed, giving up its latent heat, thereby evaporating additional raw water. The operation is continuous, a small amount of brine being continuously discharged to waste through the heat exchanger system. Figures 3 and 4 illustrate the principle of thermocompression distillation.

Compression type distillation equipment is capable of producing well in excess of 100 lb. of distilled water per lb. of fuel consumed in the power unit. Recent design has substantially increased economies now realized. Compression distillation equipment is somewhat more complicated than direct oil-fired equipment, requiring a highly skilled operator, but once the equipment is in operation it requires no more

attention than the less economical equipment.

Considering the magnitude of the supply problem, the importance in attaining maximum economy cannot be overemphasized. There is every indication that compression type distillation equipment is the ultimate in distillation. It is evident that this problem offers a most promising field for continued research. Recent technological development in sea water distillation has made available equipment which should have numerous industrial applications during the post-war period.

ION EXCHANGE

The development of modern ion exchange materials has made possible the design and construction of water desalting equipment which removes ionizable salts from water without the introduction of by-products by a process which in operation is comparable to filtration.

These desalting systems generally

consist of two units; the first, a bed of a material having the property of removing cations from solution by exchanging hydrogen ions for the sodium, calcium, magnesium, or other bases present in the water; and the second unit, a bed of an anion-active material that removes the mineral acids which the cation removal agents sets free by exchange of these acids with hydroxyl ions. When influent waters containing several thousand p.p.m. of salt are treated in this way, the results are unsatisfactory.

A desalting system has been developed commercially for brackish waters having total dissolved solids concentration as high as 7,500 p.p.m. This system produces effluent water which is substantially neutral. The system consists of four treating units operated in series. The first unit, as in the conventional process, consists of a cation-active material operating in the hydrogen cycle; the second unit, an anion-active material activated with a strong base; the third, a cation-active material also operating in the hydrogen cycle; and the fourth, an anion remover which has been so treated during activation or regeneration that its effluent is substantially neutral.

In this system, the fourth bed is regenerated with sodium bicarbonate solution, so that the bed is what is called bicarbonate activated to distinguish it from a soda ash or caustic soda activated bed, which is said to be hydroxyl activated. The second cation removes additional quantities of sodium ion both free and combined and it delivers to the fourth bed an influent which is acidic. When this acidic influent reaches the anion bed, the fixed mineral acids are removed and the free sodium ions, formed by splitting of neutral salts, are neutralized by the bicarbonate ion set free in the bed.

The advantages of such a system are:

first, a capacity for ion removal of both the cation and anion units is definitely increased, as the first cation and first anion beds can be operated far past initial breakthrough of salt; second, rinse water losses are extremely low, as no water is wasted in washing the last traces of salt from the beds; and third, the effluent is practically neutral, or slightly acidic, due to the presence of carbonic acid.

An ion exchange unit designed in accordance with the principles described above, and as a mobile unit, has been constructed and is under service test. This investigation is intended to show the military utility of this process and to determine its feasibility for both field and fixed installations. Although the military value of this improved ion exchange process remains to be proved, its potentialities are apparent.

PROTECTIVE COATING SYSTEMS

Studies pertaining to corrosion control of metal water tanks have resulted in development of protective coating systems which will satisfactorily withstand water immersion. Valuable assistance in this work was received from the Technical Advisory Committee, Federation of Paint and Varnish Production Clubs. Considering that corrosion is a universal problem, it is believed that the results of this work may have general application.

It is of paramount importance that metal surfaces be clean and free of all scale and rust prior to painting. Sandblasting is the preferable method of surface preparation. Satisfactory results may be expected using 6 lb. of Ottawa sand per sq. ft. of surface at 100 lb. per sq. in. pressure. In addition to cleaning the surface effectively, the sandblast provides an excellent "tooth" for the paint film to adhere to.

Wire brushing may be used for surface preparation in lieu of sandblasting, but vigorous rubbing of the surface

with suitable abrasives is required. Following brushing, the surface is further cleaned with naphtha or turpentine for removal of grease and oils. Phosphate treatment of the cleaned surface is recommended. This consists of applying a 5 per cent phosphoric acid solution and allowing it to dry for one hour after which the surface is washed with warm water and thoroughly dried before painting.

A number of anti-corrosive materials were investigated and tested resulting in the conclusion that synthetic resinous compounds were best suited for use on truck and trailer-mounted metal water tanks. The phenolic, vinyl, and alkyd synthetic resins were thoroughly investigated and the phenolic resins in the unmodified form were found to possess the most satisfactory properties for this purpose.

The 100 per cent phenolic thermosetting resin, due to its heat-reactive property or tendency to polymerize into an infusible and insoluble condition when heated, was superior to other organic coatings tested. Five coats of this material are recommended, which give a film approximately six mils in thickness. Each coat is cured with hot air, the curing schedule varying from 200° F. for 30 minutes on the first coat to 375° F. for six hours as the final bake. Methods used in curing this type resin are important in that temperature may be regulated to control flexibility and impermeability of the finished coating. Corps of Engineers *Specification No. T-1690*, entitled "Protective Coating System for the Interior of Potable Water Tanks," gives details of this system.

Inasmuch as facilities are not always available for application of the thermosetting, phenol-formaldehyde type coating, there was a need for an air drying coating system. Two types of paint were developed for this purpose which make use of unmodified, oil soluble

varnish resins. These are considered as alternates to the phenolic thermosetting coating. These two types are described in Corps of Engineers *Specification No. T-1715A* designated as "Protective Coating Materials and Application for the Interior of Potable Water Tanks."

Type I paint is an air drying coating which is pigmented with zinc dust and zinc oxide, 75 per cent by weight. The vehicle is of the unmodified para-phenyl-phenol-formaldehyde resin in linseed oil, having a 25 gal. oil length. The second type air drying paint contains 35 per cent iron oxide pigment by weight. The vehicle for Type II has a 25 gal. oil length and consists of the unmodified para-phenyl-phenol-formaldehyde resin in china wood oil.

The exceptional inhibiting properties of the zinc dust-zinc oxide paint and the covering properties of the iron oxide paint place these two materials among the best air dried protective coating systems tested. They possess the advantages of application by either brush or spray over a surface treated by wire brushing and they are readily cured by natural ventilation when time permits.

TREATMENT OF WATER CONTAMINATED WITH TOXIC MATERIALS

Possible denial of field water supplies through their contamination with toxic materials has long been a source of concern to the responsible agencies. That the situation has never really arisen makes the problem only more complex since it must be handled entirely on a speculative basis, theorizing such matters as possible contaminants, amounts expected, and practicality of treatment. Yet insurance measures against this potential danger cannot be neglected. Recent trends in warfare, such as the attention given reservoirs in Hong Kong and in the Ruhr district of Germany, coupled with the widespread use of non-toxic but nauseating bone-oil to

invalidate precious water points in the Tunisian campaign, emphasize the potential part water may play in war.

Consideration given to the development of treatment methods for Army field use must be confined to rational and practical viewpoints. A vast number of poisonous compounds are known, especially in the organic field, but a critical survey of these substances indicates that most could not be successfully employed as water contaminants. Some are not sufficiently soluble to produce toxic effects while others hydrolyze rapidly and become impotent. In the drug field alone, there are scores of poisonous compounds whose production difficulties, cost, and availability preclude their use in quantity. The more important substances remaining after preliminary eliminations include arsenic, cyanides, and the heavy metal salts among the inorganic compounds, and alkaloids, phenols, glucosides, phyto-toxins, organic arsenicals, and the chemical warfare agents in the organic field.

The field treatment of water contaminated with toxic materials such as alkaloids, cyanides, inorganic arsenicals, glucosides, and the heavy metal salts is chiefly of academic importance since they would be encountered only in isolated instances of deliberate, premeditated sabotage. Detection alone suffices here, and in place of treatment such supplies would be by-passed in favor of others or water could be hauled in by motor transport from other producing sources in the area. Treatment only becomes necessary when all available sources are contaminated. This might occur if chemical warfare broke out and contamination of watersheds, surface supplies, and small reservoirs resulted from the use of airplane sprays or gas shells disseminated in either dust or liquid form.

The non-persistent chemical warfare agents present no great danger to water

supplies, nor do the irritant smokes which contain arsenic but are difficultly soluble in water. Of chief concern are the vesicant agents toxic in water whose persistency could effect contamination of watersheds: Lewisite, sulfur mustard, and the nitrogen mustards. Also, a retreating army forced to abandon stores of these agents might still make effective use of them by jettisoning them in water supplies.

Much work has been done during the past few years investigating the removal of different toxic materials from water. For Army use a simple universal method is required, it being impractical to adopt several specific treatment processes for use with individual contaminants. Standard water works procedures alone are of value here, and throughout past work activated carbon has received the preferential consideration for this purpose. Activated carbon will adsorb toxic organic contaminants from water although it is not effective in the removal of inorganic cyanides, arsenic, or heavy metals. These, however, were discounted from consideration on other grounds.

The carbon treatment of contaminated water is not ideal, requiring as it does large amounts of carbon. It has, however, the virtues of simplicity, effectiveness with the most probable contaminants, and familiarity to water personnel. Recent work on water treatment at the Engineer Board has been devoted to evaluation of the commercial carbons in order to select the best all-round ones for treatment purposes. Many types of activated carbons are produced commercially for different uses, exhibiting high specificities which cause a wide variance in their removals of different materials. Of these only the finely ground grades are applicable to existing water supply equipment. Thirty-four of these carbons were evaluated against the most probable toxic contaminants, Lewisite,

FIELD WATER QUALITY CONTROL CHEST

FIGURE 5—Field Water Quality Control Chest

Levinstein mustard, and nitrogen mustards. Results showed a wide range of effectiveness, with only a few outstanding carbons. From the adsorption isotherms developed through the laboratory evaluations, the parts per million required of the best carbon to remove each part per million of agent present, above the potable limit, were found to vary from 10:1 for Lewisite to 90:1 for nitrogen mustards.

It will be evident that the importance attached to treatment of water for removal of chemical agents will be dependent on future trends of the war. The results of work described herein,

together with other studies not mentioned, afford protection against the contamination of drinking water sources resulting from chemical warfare.

PORTABLE LABORATORY FACILITIES

Routine control tests are invaluable to the operators of Army mobile and portable water purification equipment. These tests, of course, serve the same purpose with portable equipment as they do in fixed installations. However, authentic information regarding pollution sources is seldom available to personnel charged with the responsibility of operating Army water purification

equipment. Special significance is attached to control tests, and it is imperative that the operator have available means for measuring the efficacy of treatment.

A field water quality control chest, Figure 5, has been developed which is compact and relatively light. Facilities provided in this field laboratory are adequate for routine work and include specific tests for use under certain field conditions. Analytical procedures are essentially as recommended in *Standard Methods of Water Analysis*.

Design of this chest has taken into consideration the highly variable conditions experienced in a theater of operations. Tests are provided which will give a true measure of the performance of the equipment and a prompt appraisal of the quality of the finished water. This laboratory equipment makes possible technical control of the water treatment process. This control, together with constant vigilance in the inspection of the equipment and

the water supply source, make possible efficient operation.

SUMMARY

The ramifications of world-wide water supply problems are almost endless. An attempt has been made to portray typical problems of Army water supply and developments resulting therefrom. Each development described is the answer to a definite need. Under duress of war every progressive idea, whose apparent worth stands the test of complete analysis, is given consideration in consonance with its potential value. This liberal attitude promotes rapid advancement not possible in peacetime. Many developments evolving from study of water treatment requirements in various parts of the world may well find application in American water works practice. The challenge of Army water purification problems of World War II invites continued support of technologists in public health.

Nutritive Value of Brined and Fermented Vegetables*

IVAN D. JONES, PH.D., AND JOHN L. ETCHELLS, PH.D.

North Carolina Agricultural Experiment Station; and Bureau of Agricultural and Industrial Chemistry, Agricultural Research Administration, U. S. Department of Agriculture, Raleigh, N. C.

THE urgency of the food production and preservation program which has faced this nation for the past year cannot be overemphasized. This critical food problem still remains unsolved. To assist in meeting the challenge presented, research men and commercial food processors alike are investigating the possibilities offered by all methods of food preservation.

The salting or brining of food is one of the oldest preservation methods practised by man. Today we recognize that this method still offers tremendous possibilities both for commercial and home preservation of many foods.

An adequate study of the nutritive value of foods preserved by any method should properly include a comparison of the nutritive quality of the processed foods with that of the fresh produce before processing. Generally speaking, a loss in nutrients takes place whenever food is processed whether such treatment be for the purpose of preservation or for cooking for table use. Such loss is dependent upon the products receiving treatment, the processing treatments given, and the care exercised during processing.

The nutrient constituents of a food

deserving consideration in a preservation study include carbohydrates, proteins, minerals, and vitamins. There may be a loss of these constituents during food processing either through solution or leaching out of soluble constituents, or through destruction due to chemical changes during processing and storage. Also, since the brining process involves preservation as a result of, or accompanied by, microbiological activity, nutrients may be lost through utilization by microorganisms.

Throughout this discussion the term "brining" will be used whenever reference is made to the preservation of vegetables either through the use of solid salt or through the use of salt brines. Actually, in the preservation of vegetables by this method, the preservation action takes place in brine. The brine may be added as a solution of common salt or it may be formed as the result of the dissolving of solid salt in water withdrawn from the vegetables.

In this connection there seems to be a common belief that brining or salting may be done in such a manner that fermentation either will or will not take place depending upon the exact procedure followed. However, reports by the authors^{1, 2} indicate that, throughout the range of brine strength employed in vegetable preservation (upwards of 90 per cent saturation), certain types of salt-tolerant microorgan-

* Presented before the Food and Nutrition Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 12, 1943

Approved for publication as *Paper No. 173* of the Journal Series of the North Carolina Agricultural Experiment Station. Agricultural Chemical Research Division Contribution No 123.

isms are able to grow and contribute to the general fermentation.

Hence, we consider that a distinction cannot be made between brining procedures strictly on a basis that they will either permit or prevent microbiological activity (fermentation) as the result of such treatments.

The brining of vegetables is an established part of the pickle manufacturing industry. Included among those vegetables so preserved are cucumbers, onions, peppers, tomatoes, and cauliflower. These brined vegetables receive a desalting treatment prior to manufacture into the finished pickle products. Such products have a definite place in our diet but represent a small part of the total food consumed.

The brine preservation of vegetables which can be consumed as non-pickle products, and which can contribute greatly to the food value of our diet offers a distinct possibility for both commercial and domestic-scale production. Vegetables which have been brined for use as non-pickle products include beets, carrots, celery, cauliflower, cabbage, okra, snap beans, green peas, lima beans, greens, and corn. These are important sources of proteins, starch, minerals, and vitamins in the diet.

The salt concentration employed in brining varies from $2\frac{1}{2}$ to 25 per cent by weight, depending upon the vegetable receiving treatment. Sauerkraut from cabbage, or a similar product made from lettuce, turnips, or rutabagas, contains from 2 to $2\frac{1}{2}$ per cent salt. Snapbeans preserved in a low-salt brine contain 5 per cent salt. These products are used in the diet directly without desalting.

Green peas, lima beans, corn, and similar vegetables are generally preserved by the use of either strong brines or large amounts of salt (15 to 25 per cent). In commercial practice snapbeans are mixed with 20 per cent

solid salt. With such vegetables it is necessary to reduce the salt concentration materially before they are edible. The reduction in saltiness may be brought about in two ways: Either by the use of a small amount of the salted material in a large volume of soup or a similar preparation; or by soaking in a suitable volume of fresh water before preparing for table use.

The domestic brining of vegetables has been recommended over a period of years by several investigators³⁻⁷ and by the Agricultural Extension Service in many states. Although this method has been repeatedly employed for food preservation, there have been very few reports concerning the nutritive value of such food.

Losses in nutritive constituents may occur, during preservation by brining in the following phases of the process: (1) during preparation, such as peeling, slicing, or shelling, due to oxidation; (2) during blanching, as the result of leaching; (3) during fermentation as the result of microbiological activity; (4) during the curing and storage period through leaching or through chemical destruction; and (5) during desalting, largely as the result of leaching.

In general, in the brining of vegetables, the soluble carbohydrates or sugars are reduced to a low concentration either during the preservation process, or subsequently during desalting, if the latter process is required.

Brining procedures which are based on the preservation of vegetables at low or moderate salt concentrations ($2\frac{1}{2}$ to 10 per cent salt by weight) will be responsible for the complete destruction of the sugars present. This destruction occurs due to the utilization of the sugars by salt-tolerant microorganisms. Brining treatments utilizing high salt concentrations (15 to 25 per cent salt by weight) retard, but do not necessarily prevent, microbiological ac-

TABLE 1

Effect of Brining Treatments on the Protein Content of Certain Vegetables

† 1 lb brined vegetables in 1 gal. water

‡ Data by Chatfield and Adams¹¹

tivity.^{8, 9, 1} Vegetables preserved by such brining treatments may lose only a portion of their original sugar content during the preservation process. Fabian and Blum⁹ have demonstrated, qualitatively, the presence of appreciable quantities of sugar in corn preserved in brines containing 15 and 20 per cent salt and in peas preserved in brine containing 20 per cent salt after a 6 month storage period. If the brined product is used in the diet in soups or in a similar manner not requiring desalting, the remaining sugar will not be lost. Desalting will effectively reduce the sugar concentration to a very low level irrespective of the amount of sugar which may remain at the end of the fermentation process.

The fate of starch during brine preservation has not, to our knowledge, been reported in the literature. Qualitative tests by the authors demonstrated that starch was present in brined snap beans, lima beans, and peas after a 15 month storage period. This is significant in view of the fact that snap beans, immature corn, peas, and lima beans contain appreciable quantities of starch.¹¹

Certain proteins are water- and brine-soluble. These may be lost during hot water blanching, by draining away with the brine, or by desalting if these

operations are followed. Also a portion of the protein fraction is utilized by the microorganisms associated with brine fermentations.

Relative to actual losses of protein during brining, there is but limited information reported. The protein content of cabbage and sauerkraut is reported as essentially the same in the tables prepared by Chatfield and Adams.¹¹ This should be the case provided there has been neither a loss of kraut juice nor a replacement of the juice with a fresh brine.

Table 1 lists the protein content of snap beans, and immature lima beans and peas in studies conducted by the authors. In every case a loss in protein has accompanied the brining operation. The extent of loss appears to vary with the kind of vegetables brined. Also, the short blanch given snap beans materially prevented protein loss with this vegetable.

These data further indicate that, in spite of the possibilities of loss in brining as pointed out above, brine-preserved vegetables when prepared for table use showed a marked retention of protein. The retention varied from a high of 94 and 86 per cent for blanched snap beans and unblanched peas respectively, to a low of 28 per cent for unblanched snap beans from a strong

brine. Attention is called to the fact that a 35 per cent loss resulted from the blanching treatment given the fresh snap beans. Subsequent loss of protein during the actual preservation and storage in brine was very small, as has been previously indicated. Due to the fact that the protein values for the fresh vegetables were not determined, the retention figures for the last three vegetables listed in Table 1 were estimated using the protein values for fresh material reported by Chatfield and Adams.¹¹

The soluble minerals may be lost during the blanching, brining, or desalting operations. Commercial sodium chloride, however, carries a significant amount of impurities. Due to the quantity of salt employed in the preservation process, there may actually be an increase in the amount of certain mineral constituents other than salt as a result of brining. Peterson, Elvehjem, and Jamison¹² reported an increase of nearly 50 per cent in the iron content of sauerkraut as compared with the cabbage from which it was made.

The calcium content of brined snap beans, lima beans, and peas in studies conducted by the authors is listed in Table 2. A comparison of the brined with the fresh vegetable is not possible

in all cases due to the fact that analyses for the mineral content were not made for all of the lots of fresh vegetables. Included in this table for comparison are values for the calcium content of these vegetables as listed in a table by Bridges and Mattice¹³ of the mineral content of fresh vegetables. The data presented are interpreted as indicating that the calcium content of brine-preserved foods may be distinctly greater than that of the fresh vegetables which received treatment.

The influence of various food preservation methods on vitamin retention has recently received a great deal of study. Two of the vitamins, namely carotene (pro-vitamin A) and ascorbic acid (vitamin C), have received particular attention relative to their behavior during the treatments involved in food preservation. Carotene is water-insoluble, and although it may be destroyed by oxidation, it is comparatively stable. Ascorbic acid (vitamin C) is water-soluble and is rapidly destroyed by oxidation, especially enzymatically. It is also readily lost by diffusion into water or liquors employed during preservation and processing.

With reference to the behavior of carotene during the preserving of

foods by brining there is but limited information available. Richardson, Mayfield, and Davis¹⁴ reported that the vitamin A content of sweet corn preserved by salting (1 part salt to 7 parts corn by weight) and subsequently desalted and cooked was the same as raw, frozen corn. Furthermore, they found that sweet corn preserved by a brine acidified with vinegar and containing a low salt concentration possessed almost twice the vitamin A content of the raw, frozen corn taken as a basis of comparison.

Etchells and Jones¹⁵ and Etchells, Jones, and Hoffman² reported studies on changes in carotene content during the brining of blanched and unblanched snap beans; unshelled lima beans and peas; unblanched leafy vegetables such as kale, mustard greens, and turnip greens; and blanched and unblanched carrots. These data have been summarized in Table 3. The results indicate that carotene losses vary markedly with the vegetable receiving treatment. Under the conditions of the experiments, carrots showed little or no loss

of carotene, while lima beans and snap beans, brined and stored in open-headed kegs exhibited a loss of more than 50 per cent. In addition, the results indicated that the brining treatment greatly influenced vitamin retention. Snap beans brined and stored in tightly headed kegs which were filled with an acidified, low salt content brine retained from 90 to 95 per cent of their original carotene content during 7 month storage period in brine.

Blum and Fabian¹⁶ have recently reported changes in carotene content of blanched and unblanched peas, snap beans, corn, and lima beans, preserved mainly with brines of high salt content over a storage period of from 6 to 9 months. The vegetables were brined in 5 and 10 gallon open crocks stored indoors. These investigators summarized their studies in part as follows: "(1) The lower the salt concentration the greater the loss in carotene. . . . (2) Vegetables that were blanched and then salted lost more carotene . . . than did unblanched salted

vegetables. (3) Vegetables differed in their ability to retain carotene . . . during fermentation and storage." These investigators also reported a carotene loss ranging from 2 to 17 per cent during the freshening of brined vegetables (peas, string beans, lima beans, and corn) taken from brines of high salt content. Whether this loss was real or apparent cannot be determined since the relative changes in weights of the material upon desalting were not reported.

By way of summarization of the data which has been reported on carotene losses the following observations seem justified. The loss is determined to a great extent by the vegetable under treatment and the brining method employed. Blanching of the vegetable prior to brining does not appear to favor carotene retention. Treatments employing the use of acidified brines appear to favor carotene retention materially in the preservation of snap beans; however, with vegetables such as carrots or leafy greens, such benefits have not been observed.

As mentioned earlier, ascorbic acid is water-soluble and, furthermore, it is readily oxidized, especially in non-acid media. Many vegetable tissues possess enzyme systems responsible for the rapid destruction of this vitamin.

Pederson, Mack, and Athawes,¹⁷ after a detailed study of changes in the vitamin C content of sauerkraut during

commercial manufacture arrived at the following conclusions: Raw kraut (solids plus juice) during and immediately after fermentation in large vats contains approximately the same amount of vitamin C as the original cabbage. During storage in vats after the fermentation, the vitamin C content slowly decreases. This loss in vitamin C appears to be associated with the loss of an atmosphere of carbon dioxide. Canned kraut contained only from 25 to 50 per cent as much vitamin C as freshly made kraut. This loss occurs during the processing of the kraut at the time of canning and does not continue during storage after canning.

Studies by Blum and Fabian¹⁵ and Etchells, Jones, and Hoffman¹⁴ on the brining of snap beans, peas, lima beans, and corn indicate that with these vegetables vitamin C is practically entirely lost. This loss occurs during the fermentation and storage period or during the desalting required to make the product edible, providing it has been preserved by the use of a large amount of salt.

As a part of our current investigations, cauliflower was brined according to several treatments as outlined in Table 4. After a storage period of nearly 7 months, the observed changes in the total ascorbic acid content of the brined cauliflower (vegetable plus brine) can be summarized as follows: Cauliflower preserved in acidified

TABLE 4

*Ascorbic Acid Content of Cauliflower Brined According to Several Treatments
(After 7 Months' Storage in Brine in Closed Containers)*

* Vegetable covered with brine containing 5% salt and acid as shown. No additional salt added.

† Initial brine acidity approximately 0.5 per cent when calculated as lactic acid.

brines showed an approximate retention of 60 per cent for the unblanched, and 46 per cent for the blanched lots. On the other hand, cauliflower preserved in non-acidified brines showed a retention of less than 1 per cent for the unblanched, and 24 per cent for blanched lots. This experiment is a striking example of marked ascorbic acid retention obtained by particular brining methods. Substantial ascorbic acid retention was obtained not only on a percentage basis but also on a quantitative basis. The unbrined cauliflower possessed an ascorbic acid content of 67 mg. per 100 gm. and after 210 days' storage in brine, the acidified lots still retained approximately 60 per cent of that amount (based on the total ascorbic acid present in the vegetable and brine).

There is little published information regarding the effect of brine preservation on vegetables in relation to retention of B vitamins. Richardson, Mayfield, and Davis¹² found that corn preserved by salting, after desalting and cooking contained about one-fourth the vitamin B₁ content of raw, frozen corn. Preliminary work by the authors under way at this time on the riboflavin content of peas and snap beans, preserved according to a variety of brining and salting treatments, indicates that an appreciable amount of this vitamin is retained by these vegetables.

CONCLUSION

In conclusion it should be pointed out that the use of vegetables, which have been preserved in strong brines, in a manner not requiring desalting will result in the greatest conservation of nutrient constituents. This can be accomplished through the use of the brined material in the preparation of soups or certain vegetable mixtures.

In the absence of desalting, the total protein retention is high, and mineral losses are small; carotene retention is

fair and thiamin and riboflavin may be present in significant amounts. The sugars and ascorbic acid are generally lost during the fermentation period and during brine storage.

When desalting is practised in the preparation of brined foods for table use, somewhat greater losses in protein and minerals may be encountered. The desalting operation will effectively reduce the concentration of the sugars, ascorbic acid, and probably the B vitamins to a very low level. Such losses will be in keeping with degree of dilution required adequately to reduce the salt content.

It has been shown that certain vegetables which are important sources of proteins, starches, and minerals, are well adapted to brine preservation and can be used as non-pickle products. Furthermore, the data presented show that these constituents may be well retained in such brine preserved vegetables. Accordingly, at this time of acute shortages in food supplies, of limitations in labor, transportation facilities, and food processing equipment, it behooves us to give serious consideration to the possibilities of food preservation offered by the brining method.

University of Minnesota Sponsors Workshop in Community and School Health Education

From July 25 to August 5, the College of Education and the School of Public Health, University of Minnesota, offer a two week workshop to school and community health education leaders. Members will be given an opportunity to work in special interest groups as well as in sessions with the group as a whole. There will be opportunities for independent study as well as field trips, observations, and individual and group conferences.

Particular attention will be given to the organization and functioning of health councils; health education in secondary schools during the war and post-war periods; utilization of com-

munity resources for health education; and in-service training of school personnel.

The Workshop Faculty includes Ruth E. Grout, Ph.D., Harold H. Walker, Ph.D., Eva G. Donelson, Ph.D., Ruth B. Freeman, R.N., Helen M. Starr, Donald A. Dukelow, M.D., and Harold K. Jack.

Registration procedure, fees and information with regard to working or living facilities can be obtained from Ruth E. Grout, Ph.D., Associate Professor, College of Education and School of Public Health, 121 Millard Hall, University of Minnesota, Minneapolis 14, Minn.

Factors Affecting Germicidal Efficiency of Chlorine and Chloramine*

CAPTAIN GEORGE R. WEBER, SN.C., AND
LIEUTENANT COLONEL MAX LEVINE, SN.C., F.A.P.H.A.

*Sanitary Corps, Army of the United States, Station Hospital, Fort Belvoir, Va.;
and Brooke General Hospital, Fort Sam Houston, Tex.*

REPORTS in the literature disclose a marked divergence of opinion on the relative germicidal efficiency of chlorine and chloramine. Rideal (1910) observed that when an equivalent of NH_3 was added to sodium hypochlorite (1 per cent available chlorine) made by electrolysis, the phenol coefficient rose from approximately 2 for the hypochlorite to 6 for the ammoniated solution (chloramine). It should be noted that the solutions employed were distinctly alkaline.

During World War I difficulties in obtaining an adequate supply of chlorine led Race (1918) to utilize ammonia in conjunction with chlorine for sterilization of the water supply of Ottawa, Canada, with a view to conserving chlorine. He reported experiments in which it was observed that ammoniated bleach solution containing 0.2 p.p.m. available chlorine and 0.1 p.p.m. ammonia was as effective a germicide as was 0.6 p.p.m. available chlorine when employing bleaching powder alone.

Tilley (1920) observed that addition of ammonia to Dakin's solution resulted in an increased germicidal

efficiency whereas when ammonia was added to chlorinated water a drop in germicidal properties was effected.

Holwerda (1928) and Gerstein (1931) studying the germicidal efficiency of chlorine-water (with and without addition of ammonia) reported that the germicidal properties were greater when ammonia was not present.

Charlton and Levine (1937) suggested that the conflicting reports in the literature on the germicidal efficiencies of chlorine and ammonia-chlorine (chloramine) solutions might be reconciled if influence of reaction (pH) on the disinfecting properties of these two types of chlorine compounds was taken into consideration.

The objectives of the following brief report are to present data on the relative effects of such factors as (1) presence of ammonia, (2) reaction (pH), (3) concentration, and (4) temperature, on the germicidal efficiencies of chlorine and chloramine, in the absence of organic matter.

TECHNIC

The test organism employed was a suspension of *Bacillus metiens* spores prepared in the following manner: The growth from 20 day-30° C. agar slant cultures was washed off in Butterfield Formula C water and filtered through Whatman No. 2 filter paper to remove clumps. The filtrate was then heated

* Based on data from laboratories of the Department of Bacteriology and the Engineering Experiment Station, Iowa State College, Ames, Iowa. Presented before the Engineering Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 13, 1943.

at 80° C. for 10 minutes to destroy vegetative cells. This spore suspension, stored at 5° to 10° C., did not disclose any appreciable change in resistance to chlorine for a period of over a year and therefore lends itself particularly well to comparative studies over a long period of time. Just prior to use a portion of the suspension was diluted to approximately 20 million viable spores per ml.

Previous observations had disclosed that the reaction of alkaline unbuffered chlorine solutions tends to become more acid on exposure to air and stirring. All experiments reported herein were therefore carried out in M/20 concentration of appropriate buffers at desired reactions (pH), which were determined with the glass electrode. All water employed in the following experiments was ammonia-free when tested with Nessler's reagent.

Chlorine solutions were prepared by diluting a saturated stock solution made by passing gaseous chlorine into ammonia-free water. This saturated chlorine was kept in a glass stoppered bottle painted black on the outside and stored in a refrigerator at approximately 10° C. Under these conditions the chlorine content was found to remain quite constant. Ammonium sulfate was the source of ammonia, but all computations are made as NH_3 .

The procedure for determining germicidal efficiency was briefly as follows:

To 75 ml. of an appropriately buffered solution, containing a desired concentration of NH_3 , was added 25 ml. of chlorinated water containing the desired concentration of chlorine, and the flask containing the mixture was placed in a water bath. One ml. of the spore suspension (diluted so as to contain about 20 million viable cells per ml.) was placed into 100 ml. of the test solution which was being constantly stirred. (This would yield an

initial inoculum of one million viable cells per 5.0 ml. of the test solution. The number of viable spores was determined by plating a portion of the spore suspension on nutrient agar.) At the time that the spore suspension was introduced into the disinfecting mixture, the concentration of available chlorine was determined for a duplicate sample by titration with sodium thiosulfate in acid solution.

At desired time intervals, 5 ml. portions were withdrawn and placed in 45 ml. of sterile water containing sufficient sodium-thiosulfate to neutralize any residual chlorine, and the number of surviving bacteria was ascertained by plating on nutrient agar (24 hour 30° C.).

Curves were then made by plotting the logarithms of the percentage of survivors against the period of exposure in minutes, and the time for effecting a reduction of 99 per cent of the exposed spores was read from the curves and designated as the killing time (K.T.).

The question might readily be raised as to why spores were used and whether the results are applicable to water sterilization. With reference to the first question, it might be pointed out that chlorine is so effective a germicide that when employing vegetative cells the rate of death is so high (and the concentrations of chlorine employed necessarily being very low and therefore subject to wide errors in determination as well as to combination with traces of such compounds of ammonia which might inadvertently be present), that observations on rates of death and the effects of variations in temperature and reaction or concentration on these rates would be extremely difficult to carry out.

In contrast to this, by utilizing spores, it is feasible to employ high concentrations of chlorine which would not be affected appreciably by traces of impurities; studies over a wide range

of reaction, concentration, and temperature, are possible and the rates of death are sufficiently low so that patterns of the survivor curves may be readily observed. Furthermore, it is very difficult to obtain vegetative cells of uniform resistance; whereas the spore suspension employed was found to be strikingly uniform in resistance to chlorination and could therefore be employed over a long period of time for comparative studies.

As to the question whether the results with spores would be indicative of what might be expected with vegetative cells, it might be pointed out that survivor curves obtained by the authors for spores exposed to chlorine and chloramine were later confirmed by Schmelkes for *Escherichia coli* and that the relative efficiency of chlorine and chloramine reported for spores was recently found to hold for vegetative cells. Thus, Weber, Bender, and Levine (1940) reported that *B. metiens* spores exposed to approximately 22 p.p.m. available chlorine (as hypochlorite) were killed in 3 minutes, whereas it required about 28 times as

long (approximately 85 minutes) when the same concentration of available chlorine was employed as chloramine. Streeter (1943) reports a killing time of 2-3 minutes for *E. coli* when employing 0.05 to 0.1 p.p.m. chlorine as compared with 40 to 90 minutes for the same concentration of available chlorine as chloramine. The relative killing times of chlorine as compared with chloramines for spores and vegetative cells, respectively, were therefore quite similar.

SURVIVOR CURVES FOR DISINFECTION WITH CHLORINE AND CHLORAMINE

In Table 1 and Figures 1 and 2 are shown results illustrative of the rates of death of spores exposed to chlorine and chloramine. In survivor curves for disinfection with chlorine, there are exhibited distinct periods of lag in rates of death—very prolonged when employing high alkaline solutions, low temperatures or low concentrations—followed by progressively increasing death rates. Thus, with chlorine at pH 7, 24 per cent of the exposed spores died in the 1st minute, 49 per cent of

those which survived 1 minute died in the 2nd minute, and 97 per cent of the then remaining cells died in the 3rd minute of exposure. In the series with chlorine at pH 10, there was no decrease in bacterial count for 2 hours. This was followed by a progressively increasing rate of death. Thus, during the 3rd hour, only 6 per cent of the survivors after 2 hours were killed; 24 per cent of the spores which survived for 4 hours were killed in the 5th hour; whereas of those which survived 6 hours, 66 per cent were killed during the 7th hour of exposure.

In contrast to these curves of increasing death rates observed with chlorine (Figure 1), disinfection with chloramines discloses but short lags followed by quite constant death rates throughout the period of disinfection, so that the survivor curves are practically straight lines (Figure 2).

EFFECT OF AMMONIA ON CHLORINE RESIDUAL

In Table 2 are shown the residuals remaining 60 minutes after addition of approximately 25 p.p.m. available chlorine to solutions containing various

† To nearest 0.1 p.p.m.

concentrations of ammonia (added as ammonium sulfate) and buffered at reactions pH 5 to pH 10. The losses in residual chlorine per p.p.m. ammonia added are also indicated. It will be noted that when the ratio of chlorine to ammonia was high (12.5/1 and 50/1) there was considerable loss of chlorine (approaching about 7.5 p.p.m. chlorine lost per p.p.m. ammonia added) and that this loss was greatest in solutions near the neutral point; but, as the relative concentration of ammonia increased (ratio of chlorine/ammonia = 4.2/1 or less) the loss of chlorine became negligible. In general, if the concentration of NH₃ is less than about one-eighth that of the available chlorine, NH₃ will be oxidized and the chlorine residual (which will be reduced in proportion to the quantity of ammonia present) will consist of hypochlorite. The effect is therefore merely to reduce the concentration of the active germicide but its nature is unaltered. If, however, the concentration of ammonia is more than one-quarter that of available chlorine, then chloramines will be formed and the effect is

to change the nature of the germicide, whereas the concentration of available chlorine is only slightly altered. With a chlorine/ammonia ratio of 4.2/1 the available chlorine is presumed to exist as chloramine, the relative concentrations of the mono and dichloramine being a function of the reaction.

EFFECT OF REACTION ON GERMICIDAL EFFICIENCY OF CHLORINE, CHLORAMINE, AND CHLORAMINE WITH EXCESS AMMONIA

Observations were made at reactions of pH 5 to pH 10, employing the following solutions to which were added chlorinated water to yield approximately 25 p.p.m. available chlorine.

Series I. Buffered water (chlorine as hypochlorite)

Series II. Buffered water containing 6 p.p.m. NH₃ (chlorine as chloramine)

Series III. Buffered water containing 18 p.p.m. NH₃ (chloramine with excess NH₃)

The test organism was introduced into the disinfecting solution 15 minutes after addition of chlorine and the temperature was maintained at 20° C.

TABLE 3

Effect of Reaction (pH) on Germicidal Efficiency of Chlorine, Chloramine, Chloramine with Excess Ammonia

* See Table 2

† At time of addition of test organism (15 minutes after addition of chlorine)

In Table 3 are shown the initial residual chlorine concentrations (at time of introduction of test organisms) and the killing times (time to kill 99 per cent of the exposed spores).

Comparing Series I (chlorine) with Series II (chloramine), several things are strikingly evident. For chlorine, germicidal efficiency was a direct function of reaction. The killing time varied slightly, from 2.1 minutes at pH 5, to 7.6 minutes at pH 8, thereafter increased very rapidly to 58 minutes at pH 9, and 570 minutes at pH 10.

In marked contrast to this, there was no significant difference in the killing times (83 and 89 minutes) for chloramine (Series II) in the range pH 6 to pH 8, whereas for solutions more acid (pH 5) and more alkaline (pH 9 and pH 10) the killing times (168 and 186 minutes) were approximately double those in the range pH 6 to 8.

The effect of presence of a large excess of ammonia on germicidal efficiency of chloramine may be noted by comparison of Series II and III. At pH 7 the killing times (89 and 84 minutes) were the same within limits of experimental error of determination. Chloramine in the presence of a large excess of ammonia (Series III) was

more effective at pH 5 and pH 6 but distinctly less effective as a germicide at pH 9 and pH 10 than was chloramine solution in which there was not present any excess of ammonia.

The data for chlorine (Series I) and the chloramine (Series II and III) are shown graphically in Figure 3 where the logarithms of the killing times are plotted against the reactions (pH). The curves for chlorine and chloramine cross at pH 9.4. At reactions more acid than pH 9.4 chlorine is markedly more effective, whereas at more alkaline reactions chloramine is the more efficient. In this connection it might be pointed out that the increased germicidal effect produced by addition of an equivalent of ammonia to electrolyzed hypochlorite solution, first noted by Rideal (1910), was probably associated with the fact that he was working with sodium hypochlorite which was quite alkaline.

The greater germicidal efficiency of chloramine as compared with hypochlorite at reactions more alkaline than pH 9.4 may be particularly significant in conjunction with chlorination of softened water and water treated by the excess lime process, if reactions of about pH 10 are maintained.

FIG. 3 EFFECT OF REACTION (pH) AND AMMONIA ON GERMICIDAL EFFICIENCY OF CHLORINE (20°C)

EFFECT OF CONCENTRATION ON GERMICIDAL EFFICIENCY OF CHLORINE AND CHLORAMINE AT VARIOUS REACTIONS

Killing times for each of four concentrations of chlorine and chloramine were determined for reactions pH 10, pH 7, and pH 5 at a temperature of 20°C. The data are shown in Table 4.

With chlorine, the results were very consistent. They indicated that by doubling the concentration, the time required to kill 99 per cent of the exposed spores was reduced by 45 to 50 per cent or, to put it conversely, as the concen-

tration of available chlorine was cut in half the period of exposure (or killing time) was increased 1.8 to 2.0 fold. This seemed to hold true for each of the reactions under observation.

The results were more erratic with chloramine but indications were that the effect of varying concentration was somewhat less marked than was observed with chlorine and that a reduction of 35 to 40 per cent may be expected on doubling the concentration, i.e., the period of exposure would have to be increased 1.6 to 1.7 fold if the concentration of chloramine were reduced by 50 per cent.

TABLE 4

† The number of fold increase in "KT" effected by a drop of 10° C.

‡ See Table 4.

EFFECT OF TEMPERATURE ON GERMICIDAL EFFICIENCY OF CHLORINE AND CHLORAMINE AT VARIOUS REACTIONS

Observations on the effect of temperature were made employing approximately 25 p.p.m. available chlorine at reactions pH 10, pH 7, and pH 5. Temperatures of 20°, 30°, 40°, 50° C. were employed for all observations with chloramine and for the chlorine solution at pH 10, but at the more acid reactions, temperatures of 0°, 10°, 20°, and 30° C. were employed for the chlorine series. The data are detailed in Table 5.

Generally speaking, the temperature coefficients seem to be relatively slightly influenced by reaction, but they are significantly different for the two compounds. Thus, with chlorine, a rise of 10° C. effected a reduction of 50 to 60 per cent in the killing time so that for a drop of 10° C. the period of exposure would have to be increased 2.1 to 2.3 fold. With chloramine, on the other hand, a rise of 10° C. is accompanied by a reduction of approximately 68 to 74 per cent in killing time; i.e., a drop of 10° C. entails a 3.1 to 3.8 fold increase in the period of exposure to effect the same bacterial reduction. The practical significance of the foregoing observations might be illustrated by the following example: If a contact period of 30 minutes at 20° C. is considered adequate for safety for a stipulated residual chlorine, the contact period would have to be raised to 60 to 70 minutes if the residual were chlorine (hypochlorite) or to 95 to 115 minutes for a chloramine residual, should the temperature of the water fall to 10° C. If the temperature of the water approached 0° C. then the period of contact for a stipulated chlorine (hypochlorite) residual would have to be increased to 130 to 160 minutes, whereas for a chloramine residual a contact period of 290 to 430

minutes would have to be employed to effect an equivalent germicidal action.

SUMMARY

A technic is described for determining the nature of survivor curves and the time required to effect a reduction of 99 per cent of *Bacillus metiens* spores exposed to chlorine and chloramine at various reactions and temperatures.

On the basis of previous findings and reports in the literature, results obtained with spores are considered applicable to those which might be anticipated for vegetative cells exposed to chlorination.

In disinfection with chlorine there was exhibited a marked lag followed by progressively increasing death rates; whereas with chloramine the rates of death were (except for a short lag) quite constant throughout the period of disinfection.

With concentrations of ammonia less than one-eighth that of available chlorine (hypochlorite) the chlorine residuals were reduced in proportion to the ammonia present but the nature of the germicide remained unchanged (hypochlorite). With concentrations of ammonia greater than one-fourth that of the available chlorine, the concentration of available chlorine was but slightly altered, but the nature of the germicide was changed from hypochlorite to chloramine.

Doubling the concentration of available chlorine reduced the killing time by approximately 50 per cent and 40 per cent for chlorine and chloramine, respectively.

A drop of 10° C. resulted in a two-fold increase in the period of exposure when employing chlorine and a 3 to 4 fold increase for chloramine, to effect equivalent germicidal action.

The germicidal efficiency of chloramine was not appreciably affected by the presence of a large excess of ammonia at pH 7, but at more acid reac-

tions its efficiency was greater; whereas at more alkaline reactions the killing power was markedly less than was observed for chloramine alone.

At reactions more acid than pH 9.4 chlorine (hypochlorite) was by far the more efficient germicide, but at more alkaline reactions chloramine was better than chlorine.

Prescriptions for Heavy Cream to be Approved by Health Officers

The War Food Administration has announced the adoption of measures to prevent the abuse of certain provisions of War Food Order 13 with regard to the prescription of heavy cream for use in the treatment of the sick. On June 2, an amendment to the Order was

issued which requires that prescriptions for heavy cream be approved "by the public health officer, or the secretary of the county medical society, of the municipality or county" where the patient or hospital desiring the cream is situated.

Housing Problems of Interest to the Public Health Engineer*

M. ALLEN POND

Sanitary Engineer (R), U. S. Public Health Service, Washington, D. C.

THE Bureau of the Census has reported that there were about 37,325,000 dwelling units in the United States in 1940.¹ Nearly 50 per cent of these were in need of major repairs or lacked inside toilets or baths (Table 1), and 940,000 rural homes had neither a toilet nor a privy. It is evident that a large part of the American public is not served by modern sanitary conveniences.

probably would exceed 2.5 billion dollars. Colean has estimated that the country could absorb anywhere from 900,000 to 1,200,000 new dwellings a year in the decade following the war and still be in need of a large amount of repair during the same period.²

There are essential differences between housing built in a peacetime program, and shelter for war workers. The former is designed to last for rela-

TABLE 1
Certain Dwelling Unit Characteristics, 1940

	<i>Urban</i>	<i>Rural *</i>	<i>All</i>
Millions of Units	23.685	13.64	37.325
Millions needing major repairs or lacking inside toilet or bath	7.085	11.139	18.224
Percentage needing major repairs or lacking inside toilet or bath	29.9	81.8	48.8

* Excluding rural units within metropolitan areas

It has been estimated that apart from replacements there is an average annual need for 500,000 new dwelling units in this country. These would be for newly formed families, and to replace structures destroyed by fire or natural phenomena. Furthermore, 10 to 15 million new dwelling units are needed to replace existing substandard housing. Translated into dollars, this means that at least 40 billions would be required to provide necessary new housing. An additional 5 million housing units should be rehabilitated at a cost that

tively long periods of time, most generally from 25 to 60 years. Planning for it can be leisurely in comparison with wartime standards, and careful attention can be paid to all details. War housing, which is admittedly temporary, generally has to be built in the shortest possible time, with the result that every expedient to prevent delay is grasped. Building materials in wartime frequently are on the critical list, and many are not available for housing. Standards for wartime construction are perforce lower than those considered to be minimal in peacetime.

It is the purpose of this discussion to point out some of the phases of any

* Presented before the Engineering Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 14, 1943.

large scale housing construction and rehabilitation program that should interest public health engineers. Many of the comments stem from the writer's experience during the past eighteen months while he has been detailed by the Public Health Service to be Sanitary Engineer Consultant to the Federal Public Housing Authority.

SANITARY ENGINEERING PROBLEMS

The sanitary engineering problems of housing are essentially those of the community. For this reason it is the policy of FPHA as well as the Federal Housing Administration to use existing public utilities wherever possible. Effective coöperation of these agencies, with the Federal Works Agency and local governments has been instrumental in strengthening the water supply and sewage disposal facilities of many communities. However, the exigency of providing shelter in the shortest possible time has occasionally necessitated the development of on-site water resources or sewage treatment plants. It is with these utilities that health department engineers should have a primary concern.

Reference has been made to the need for rapid development of projects to house war workers. Under the terms of the Lanham Act, the National Housing Administrator is authorized "without regard to . . . any federal, state or municipal laws, ordinances, rules, or regulations relating to plans and specifications or forms of contract, the approval thereof or the submission of estimates therefor . . . to make surveys and investigations, plan, design, construct, remodel, extend, repair, or demolish structures, buildings, improvements and commercial facilities."³ In order to eliminate all possible sources of delay it has been the policy of the FPHA not to submit plans to state and local authorities for approval. However, the Authority attempts to coöper-

ate closely with all interested state and local officials. In the post-war period, as before the war, public housing will undoubtedly be constructed by local authorities and will conform to all local ordinances and regulations.

WATER SUPPLY

Water is generally provided at large new housing developments for fire fighting purposes, thus assuring a supply that is quantitatively sufficient for domestic purposes. Public health engineers will usually be concerned with questions relating to the safety of the source, the degree of treatment, and the construction and operation of plants and distribution systems, when such facilities are built to serve new housing.

For instance, the FPHA was recently concerned with difficulties in sterilizing water mains at a war trailer project. The supply, taken from a potable source, as it entered the project mains was slightly contaminated. Samples collected from frost-proof hydrants at the extremities of the system showed serious bacteriological contamination. There were no physical evidences of faulty construction, and the system on-site was superchlorinated seven times, with dosages ranging up to 200 p.p.m. of available chlorine. Contact periods exceeded 24 hours. Samples continued to be unsatisfactory. The questions were asked: Should these badly needed trailers be opened for occupancy before there is bacteriological evidence that the water supply is free from contamination? If not, where will the essential war workers in this isolated, crowded community be housed? Is it the state's responsibility to install an emergency chlorinator at this project? Provision was subsequently made for permanent chlorination, thus answering these particular questions. However, they are typical of others that are raised

periodically concerning war housing water supplies.

Arrangements have recently been made with several state health officers to examine water samples collected by FPHA project managers. In at least one state, samples are routinely collected by health department representatives from housing projects served by FPHA-owned water supplies. Do health department engineers regularly arrange for this service for privately built, multiple-unit housing developments served by other than public water supplies?

In some states, builders are required to submit plans for the development of on-site water supply and sewage disposal facilities to the state health department for review and approval before construction begins. This is a desirable practice and should be universal.

SEWAGE AND REFUSE DISPOSAL

Health officials are constantly confronted with problems arising out of the disposal of sewage from dwellings located in areas where sewers are not available and cannot be justified. If housing developers consulted appropriate health authorities when selecting sites and if health departments were prepared to review all plans for and supervise the installation of on-site sewage disposal systems, most of these problems would never arise. However, until public health engineering services are more generally provided, it is evident that sewage nuisances will occur frequently. This is particularly noteworthy in light of the sewage disposal needs expressed above.

The collection and disposal of refuse from suburban and small town homes present particular difficulties. It would doubtless be possible to establish satisfactory refuse disposal systems in many places where extensive housing is built, if public health engineers could co-

operate with housing officials during the housing development stage as is the case now with FPHA projects. It has been evident in many war-boom areas that the lack of a suitable local catalyst has prevented the crystallization of a refuse disposal system. Conversely, competent local sanitarians have stimulated the organization of satisfactory wastes disposal schemes in several places.

STRUCTURAL PROBLEMS

Outmoded and highly restrictive plumbing legislation may seriously interfere with the extension of decent indoor sanitary facilities to tenants of low rent housing. Connolly has pointed out the important factors to be considered in designing plumbing for low cost housing,⁴ and a subcommittee of the now defunct Central Housing Committee has developed a comprehensive plumbing manual for use by federal construction agencies.⁵ Plumbing codes generally should be brought up to date, both to protect the public health and to permit uses of materials which will give better and more lasting plumbing. Unless many city plumbing codes are modernized it is likely that progress in providing inside plumbing in the thousands of structures that are otherwise rehabilitable will be seriously impeded if not entirely blocked.

During the present national emergency it has been necessary to lower plumbing standards for temporary housing.⁶ However, an attempt was made to preserve those parts of codes devised to protect the public health.

New and existing houses in many American communities should be rat-proofed. There is an adequate economic reason for doing this, and in many places the hazard of rodent-borne disease is serious. Private builders probably will not plan for rat proofing if official pressure is not exerted by the health department.

The Royal College of Physicians of London has recently drawn up a memorandum entitled "*Design of Dwelling Houses*" that contains much interesting information concerning desirable structural characteristics for homes.⁷ Furthermore, the document reveals the need for intensive research, much of which would involve physical and physiological studies that cannot readily be conducted under state and local health department auspices. However, studies of the technics of housing sanitation might be carried out by engineers attached to such agencies.

APPRAISAL OF URBAN HOUSING NEEDS

Many of the needs for new housing are bound to be met in the post-war decade. The slum clearance and public housing work of the 30's will doubtless be continued with new vigor, as will the extensive private home building program that is so much a part of America. In addition, the elimination of temporary war housing projects will involve considerable work.

It is essential that careful planning for new housing be conducted on federal, regional, and local levels. The National Housing Agency, parent organization of FPHA and FHA, is logically concerned with national planning. Equally responsible for local planning are town, city, and county governments. The time to do that planning is now.

In order to do successful planning, specific data on housing needs should be available.

A useful technic for studying the quality of urban housing, and indirectly the need for new construction and for the rehabilitation, has been developed by the Committee on the Hygiene of Housing of the A.P.H.A.⁸ It has been tested in New Haven, Stamford, and Waterbury, Conn., and in Portland, Me., and is ready to be applied elsewhere.

The committee believes that health officers should take an active part in planning housing for health.⁹ It is desirable in studying housing needs, to have close collaboration between health workers and other local officials, including housing authorities and city planning experts. The appraisal technic of the Committee on the Hygiene of Housing appears to be the most effective tool yet devised for this purpose.

The cost of a housing survey using the technic mentioned above is low. Complete data on 1,280 dwelling units in New Haven were collected and processed at an expenditure of 4 man-months of inspectors' time and between 3 and 4 months' time of one clerk.⁸ This would be at a rate of approximately \$.80 per dwelling unit. Considering the value of the data for planning for new housing, the rehabilitation of existing homes, and the development of a satisfactory housing inspection program, this is a low unit cost. The appraisal technic can be applied on a sampling basis in known substandard areas, thereby further limiting the total expenditure for any given community.

No health department can afford to carry on without planning and expect to make progress. The objectives of any health program must be clearly understood. It is reasonable to expect that future housing inspection work conducted by health agencies will involve not only consideration of minor structural and maintenance problems, but also broad questions of slum clearance and rehabilitation. It is axiomatic that the first job of a new health unit is to conduct a reconnaissance survey. Why not a similar study of housing?

COÖPERATION BETWEEN HEALTH AND HOUSING AGENCIES

It has been charged that the builders of housing are uncoöperative and fail

to seek competent technical assistance from health departments. This comment unfortunately contains an element of truth.

However, there is another side to the story. Health departments have not always been able and willing to give good technical guidance to the housing construction industry. There is too often a tendency for "health authorities" to tell the public what to do without saying how to do it. Housing is a big business. Its representatives are generally willing to be guided by competent technicians. But it wants guidance of a positive nature.

Some health officers have been mistaken in considering that FPHA projects are government reservations and therefore not subject to health department inspection and supervision. This assumption is wrong, and the Authority is on record as requesting the services of public health agencies in many communities.

Adequate control of housing from the viewpoint of public health requires many forms of protection.¹⁰ Standards for new construction and the rehabilitation or conversion of existing structures are essential. Maintenance and occupancy standards must be enforced. But it is practically impossible to accomplish much in the improvement of housing in a community unless there are satisfactory housing regulations. Health, building, and other officials need authority to make a frontal attack on the numerous problems that confront them all. Such authority usually will result only from the enactment of a local housing code.

The development of modern housing regulations in every locality should be among the first pieces of work of health departments in the post-war years. Public health engineers should be vitally concerned with the content of such legislation, and they have a responsibility to promote it.

DUTIES OF HEALTH DEPARTMENT HOUSING ENGINEERS

The Public Health Service has been cooperating closely with FPHA ever since that agency was created by Executive Order on February 24, 1942. At present, 11 engineers are on full-time detail to FPHA from the Service. One is on duty in the Central Office, and there is also one in each of the ten regional offices of the Authority. These sanitary engineer consultants are concerned with all manner of environmental sanitation problems occurring in war housing. It has been their experience that, if there can be effective cooperation during the development of plans and the selection of sites for multiple-unit housing, many of the sanitation problems that might develop are automatically prevented. Probably the most significant contribution of these men is made in connection with the selection of sites.

The idea of detailing health department engineers full-time to housing work is not new. The Connecticut State Department of Health has had a housing engineer in its Bureau of Sanitary Engineering for several years.

The duties of a housing engineer in a state department of health involve:

1. Analysis of existing housing laws and regulations with a view to the development of new legislation for state and local enactment
2. Training of local public health engineers and sanitarians in modern housing inspection technics
3. Assisting in the organization of local housing surveys
4. Review of plans for major new housing developments (particularly in communities lacking local health services)
5. Consultation with governmental officials and citizens concerning housing sanitation

These are time-consuming jobs. However, they strike at many of the roots of our housing problem, and for that reason are essential.

There is little evidence at present

that city or county health departments would be justified in employing housing engineers as such, except in the largest communities. However, there are numerous opportunities for local public health engineers to concern themselves with housing. These include (in co-operation with public housing officials and private home builders):

1. Development of a satisfactory housing code
2. Organization of a comprehensive inspection program including a plan for evaluating the need for new housing and for the rehabilitation of existing structures
3. Review of plans for new construction
4. Inspection of new construction, particularly of sanitary facilities being provided therein

These duties are obviously important, but they have not always been given the attention due them. It is to be hoped that in the post-war world public health workers will assume their responsibilities in these respects, and that they will take positive action to promote housing for health.

Further Evaluation of EC Medium for the Isolation of Coliform Bacteria and *Escherichia coli**

C. A. PERRY, Sc.D., F.A.P.H.A., AND A. A. HAJNA

*Director of Bacteriological Laboratories; and Associate Bacteriologist;
Maryland State Department of Health, Baltimore, Md.*

AT the St. Louis meeting of the American Public Health Association in October, 1942, the authors had the pleasure of discussing their experience with a new EC medium (buffered tryptose lactose bile-salt $\frac{7}{8}$) for the isolation of coliform bacteria at 37° C. and of *Escherichia coli* at 45.5° C.¹ In the examination of 147 samples of drinking water of various types, not a single false presumptive was encountered among 1,176 gas tubes while 58.5 per cent of false presumptives were obtained with standard lactose broth. At the same time 14.2 per cent more of the EC tubes were positive for coliforms. The medium was found to have comparable sensitivity to Mallmann and Darby's² LST (lauryl sulfate tryptose) medium when tested with 33 stool specimens and 25 samples of raw sewage.

Evaluation of the medium in laboratories other than that of the authors, seemed desirable. However, due to war conditions many laboratories were unable to participate in such an evaluation. Results are presented here from eleven laboratories including that of

the authors. Some results from the participating laboratories have had to be excluded because of technical errors.

The completed test for coliform bacteria was used in this study. It is well known that the more steps involved in a routine examination, the greater the number of errors, and it is probable that some of the results presented here are highly inaccurate due to such technical errors. If the short confirmatory procedure of transferring a loopful of culture from the primary gas tube to a secondary tube of brilliant green bile broth had been used, such errors would probably have been largely eliminated and a far better evaluation of the several media might have been obtained. The good results obtained in some laboratories indicate the potential values of these media.

It appears that in actual routine work an unconfirmed presumptive test with either the EC medium or the LST medium is probably much more reliable than the standard completed test. The use of a single primary medium such as EC or LST as a completed test would be valid, however, only if gas resulting from actual fermentation of lactose is recorded. With both these media abundant gas is almost invariably present within 24 hours if positive for any bacteria of the coliform group. Slight traces (less than 1 per cent) of gas in these two media without

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 13, 1943.

† "EC" refers to *Escherichia coli* though the medium is just as valuable for isolation of coliform bacteria at 37° C. as it is for the isolation of *Esch. coli* at 45.5° C.

effervescence are probably nonspecific gas, for it is well known that such traces of gas may result from various nonspecific causes. It is a routine practice in the authors' laboratory* to test for questionable gas by shaking. If definite fermentation of lactose has occurred, effervescent gas will be very obvious. Slight traces of gas have never been found by the authors in either EC medium or LST medium after 24 hours' incubation unless slow lactose fermenters are present. Whenever coliform bacteria have been present, abundant gas has been produced. Slight traces of nonspecific gas without effervescence do occur in some laboratories for the reasons noted. Such traces of nonspecific gas can usually be avoided by suitable technical precautions and their nonspecific nature determined by shaking. Traces of gas, however, should always be confirmed.

In order to show the wide variations in results obtained by the participating laboratories, the results were separately compiled. The results also were compiled according to the type of material under examination. In accordance with our earlier report,¹ very few false presumptive tests were obtained with the EC medium by bacteriologists in five of the participating laboratories (A, B, C, D, and E). Only six, or 0.6 per cent, false presumptives were found among 945 EC gas tubes. It is doubtful, however, if the six so-called false presumptives were really false, as slow-lactose-fermenters were recovered from two similar tubes and possibly were present in these six tubes had they been available for critical reexamination. The results with the LST medium were also excellent. With the same samples, 654 LST gas tubes were obtained against 650 with the EC medium. There were no false positive EC gas tubes, however, while 15, or 2.3 per cent, were found with the LST medium. False "false presumptives" due to

slow-lactose-fermenters, could be expected to be the same with both media. The percentage of false presumptives using standard lactose broth (SLB) varied from 0 to 97.9 per cent and averaged 24.2 per cent.

No evaluation of the lauryl sulfate medium at 45.5° C. was attempted but the EC medium was found highly specific for *Escherichia coli* at this temperature. While a small percentage of false presumptives was encountered with the authors' original modified Eijkman medium,³ only one, or 0.17 per cent, out of 603 EC gas tubes obtained at 45.5° C. failed to confirm for *Escherichia coli*.

Unfortunately, the results from six other collaborating laboratories (F, G, H, I, J, and K) were not so satisfactory. The percentages of false presumptives with Laboratory "F" were small for both the EC and LST medium and relatively small for SLB. Laboratory "G" found relatively low percentages of false presumptives with all three media and the sensitivity of the EC medium was considerably lower than that of the LST or SLB. Laboratory "H" tested all three media on samples of shellfish and of raw and chlorinated water. It is stated in the report from that laboratory that "the adoption of the LST medium as the standard medium would result in coliform indices somewhat larger than at present with SLB and that the use of the EC medium would effect a sharp reduction in the number of false presumptives." The following data have been presented by that laboratory after they had deleted certain questionable samples.

Medium	Primary Gas Tubes *	Completed Test *
SLB	9.7	4.6
LST	6.7	4.7
EC	4.7	4.4

* as M.P.N. per sample

These computations obviously were not made from the data as presented in this

report, which had from 11.3 to 24.4 per cent false presumptives for the EC medium and from 6.8 to 24.1 per cent for the LST medium. Those for standard lactose broth varied from 13.8 to 56.0 per cent. Significant data were selected.

Detailed results for each of the participating laboratories have been de-

widespread technical errors may be. Technical errors are doubtlessly as widespread in water examinations. The impossibility of evaluating any method unless technical errors can be controlled, is obvious. It is hoped that further work may help to determine the validity of these results and the exact cause of probable technical errors.

TABLE 1

Comparative Sensitivity and Specificity of EC, LST and SLB Media for the Isolation of Coliform Bacteria

* Samples of human feces, shucked oysters, milk, sewage, and various types of water

† Samples of shellfish and various types of water

leted on account of space. A summary of the results from all of the participating laboratories is given in Table 1.

The reason for the high percentages of false presumptives obtained by some of the collaborating laboratories may be due to reading tiny bubbles of air or nonspecific gas as "positive" when there is no fermentation of lactose. Such traces of gas are apt to be entrapped air or that resulting from dextrose formed by hydrolysis of lactose. Air may be forced into some tubes when running water from pipettes. Dr. Black's report⁴ on technical errors in the bacteriological examination of milk indicates how

CONCLUSIONS

The results indicate to the authors that both the LST medium and the EC medium are highly sensitive and specific media for the isolation of coliform bacteria from water, shellfish, and sewage. The EC medium has also given excellent results for isolating both coliform bacteria at 37° C. and *Escherichia coli* at 45.5° C. from milk. If errors probably due to reading gas resulting from entrapped air, hydrolysis of lactose, and often other factors can be eliminated, positive presumptive tests with both the EC medium and the LST medium have been found to be indicative of the presence of coliform

bacteria in almost 100 per cent of cases. While both the EC and LST medium are highly efficient in the isolation of coliform bacteria, the EC medium is somewhat more specific. A presumptive test reading with either the EC or the LST is obtainable which seems to be far more dependable than the usual "confirmed" or "completed" test result. Both of these media offer rapid tests of great dependability which should be of the utmost importance under war conditions and in peacetime for, when properly performed, they give highly dependable results within 24 or, at most, 48 hours.

Industrial Hygiene in the Post-War World*

JAMES G. TOWNSEND, M.D., F.A.P.H.A.

Chief, Division of Industrial Hygiene, National Institute of Health,† U. S. Public Health Service, Federal Security Agency, Bethesda, Md.

THERE can be no doubt that the war has set the stage for a new industrial era in the United States when hostilities shall have ceased. By the same token, we can clearly envision a new era of industrial hygiene in the post-war world. I am well aware that the phrase "new era" carries, somehow, a meaning of promise and optimism. But "newness" in itself never has connoted a change for the better. Post-war industrial hygiene will be just what we make it—an effective tool for the advancement of human health and welfare or solely a specialty of scientific research and medicine.

We are now at the flood-tide of war production. The industrial plant of the United States and our labor force are the largest in the world's history. Within the limits of available funds and trained personnel, the nation's industrial hygiene services both public and private have reached their peak of performance.

From this vantage, what can those of us—equipped by training and experience to anticipate problems and needs in industrial health—visualize as our future task? How can we best meet the problems and needs? Where do we go from here?

The answers to these questions are found in joint planning on the part of

all interested groups, under the leadership of those with the "know-how." But unfortunately, at a time when we most need concerted thought and action, post-war planning has become more or less a free-for-all. Diverse plans are being placed before the public, and various writers in various occupations have submitted schemes for the world of tomorrow. This being the case, I do not hesitate to enter the arena, for although any public servant nowadays expects to be dubbed "bureaucrat," I have not yet been called a "long-haired professor," and hence may be allowed to speak my piece.

DEFINING THE PROBLEM

Reliable estimates of the need for industrial hygiene services depend upon our ability to define the problem in every area of operations—plant, community, state, and nation.

At the present time, reliable data in the industrial hygiene field are scant. For example, our estimates of disabling sickness among the nation's workers and the trends in occupational morbidity and mortality are based upon a very small sample. The records submitted to the Public Health Service for analysis cover some 250,000 individuals employed in a limited num-

* Chairman's address presented before the Industrial Hygiene Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 12, 1943.

† Since this paper was prepared, the Division has become the Industrial Hygiene Division, Bureau of State Services, U. S. Public Health Service.

ber of trades. These studies constitute the best available estimates of industrial disability and are of great value in demonstrating the methods of disability reporting and analysis.

Occupational disease reporting in the United States is so inadequate as to be worthless. Twenty-five states have laws or regulations or both relating to occupational disease reporting. Other sources of data are the 27 bodies administering the various state compensation laws. But since these laws vary in coverage and in other particulars, the diseases reportable and the methods of reporting vary to such an extent that at present no comparable data can be assembled. If we are to have the epidemiologic intelligence needed in attacking any public health problem, the states will have to come to some agreement on uniform reporting of occupational diseases and will have to enact appropriate legislation.

The compilation and analysis of data on disabling sickness and occupational disease require the attention of statisticians skilled in the interpretation of mass data. Here the state vital statistics bureau or the state division of statistical services could be of enormous help to governmental industrial hygiene units and industry by providing good statistical services. This is being done with considerable success in connection with disabling sickness by the Tennessee Division of Statistical Services, a unit of the State Department of Public Health. Although the work began with a sample of industrial plants in the state, the results in valuable information on the how, when, and where of industrial disability have been such as to require an expansion of the service.

The economics of industrial hygiene is one of the most important and most neglected areas of information. There are no data available on the *total* national expenditures by all sources

for industrial health and safety services. Estimates have been made of the costs of in-plant services and a few interested industries have attempted to correlate costs of services and savings in costs of compensation, time loss, labor turnover, etc. Much work needs to be done in this field. Industry and labor, insurance companies, and governmental agencies all have a stake in the development of more complete information on industrial hygiene economics. Further expansion depends heavily on our ability to estimate the practical benefits of industrial hygiene. Better information on the costs of services might lead to the development of more effective utilization of funds, facilities, and personnel, and hence to important savings and better services.

If then, war's end presents no new problems, reevaluation of the industrial hygiene problem, improvements in epidemiologic information, and the collection and analysis of data on the costs of industrial hygiene offer a stimulus to greater effort.

POST-WAR PROBLEMS

The cessation of hostilities, however, will accentuate rather than reduce the need for industrial hygiene facilities. Although we have learned much about many of the new materials introduced during the war and scheduled for much wider use in consumer production, we will be faced with the potential hazards of entirely new processes, new types of jobs, and still newer materials.

Proper placement of workers returning from the armed forces or from war industries will be of outstanding importance, especially in relation to service-connected disabilities. We have only made a beginning in the effective adjustment of handicapped persons to industry. This war cannot be followed by blanket rejection of the physically handicapped from industrial employment. It is the responsibility of

industrial hygienists to see to it that jobs are fitted to men and men to jobs.

The U. S. Civil Service Commission has made a careful job analysis of some 2,500 occupations to determine the jobs for which service men with varying types and degrees of disability could be trained. It is expected that the findings of the study will be utilized by national and state rehabilitation services and by industry in the selection, placement, and reëducation of disabled service personnel.

Threshold training of new workers by industry and educational institutions has been introduced during the war as a means to provide quickly the all-essential man power. In the reëducation of former workers and the training of service men for industrial employment, this same method of job instruction will be used on a wider scale. Here, industrial health and safety personnel can exercise a powerful influence by introducing concurrent training in safety practices and in the recognition by supervisory personnel of potential hazards. Plans for integrating industrial hygiene with post-war vocational education and rehabilitation should be made now.

Demobilization of our armed forces and of war industries will result in an even more drastic and acute transmigration of workers and their families, with attendant social and economic dislocations that will augment the problems of medical care, particularly as it relates to industrial hygiene.

Already plans are being advanced by industry for the conversion of war establishments to consumer production. As in conversion to war production, health and safety of the workers must be considered at every stage of the transition—from the blueprint to full operation.

New industrial hygiene problems will be posed by pre-war industries now grown to giant size, and destined to find

a comparable place in the peacetime economy. Notable in this group is air transport. Much that we have learned in creating our superb United States air force can be applied to post-war aviation. But problems as yet unsolved and others anticipated will require intensified research and application of new knowledge. For example, civilian aviation and air transport will not only bring in the "air age," but also airplane accidents. While aeronautic engineering and plane production have advanced consistently in solving the problems of mechanical failure, we know very little about the human factor in airplane accidents. The selection of flight personnel, pilot fatigue, air sickness, and the physical fitness of personnel, passengers, and civilian fliers for flight—all need study. In the post-war world, these problems of aviation medicine have industrial hygiene implications that cannot be overlooked.

Other industries and processes have come out of the laboratory during the war and will be important in post-war industrial hygiene. The manufacture and processing of plastics and synthetic rubber on a large scale are here to stay. So also are welding and fabrication of light and heavy metals, x-ray inspection of industrial materials, and a dozen others. Each of these new technologies presents potential hazards of a serious nature which must increasingly demand our attention as their use expands.

The substances used in the manufacture and processing of synthetic products have been under investigation by the Division of Industrial Hygiene, National Institute of Health, for some time. Likewise, rare metals such as beryllium which have hitherto been little used in industry are still under study. As similar substances come into wider and *newer* use, research must continue and large-scale application of control methods must be envisioned in

post-war industrial hygiene work. Both industry and government should plan together now how present knowledge may be applied to consumer production.

Furthermore, developments in the post-war industries will undoubtedly see the introduction of new substances and processes. Close coöperation between industry and governmental industrial hygiene services is needed in order to eliminate the lag between the introduction of new potentially hazardous substances and the determination of their toxicity and of control measures.

The pressure of war production has made it impossible in many cases for industry to apply control measures before outbreaks of occupational disease occurred. If industrial hygiene is brought in on the ground floor of planning for post-war production, much needless human waste can be prevented.

If an industry knows that a new substance or a new process is to be important in its post-war program, now is the time to subject the problem to industrial hygiene investigation. Within the last year, the munitions industry profited by securing this type of foreknowledge. When there were only a few pounds of a new explosive in the United States, laboratory research in the Division of Industrial Hygiene and the War Department determined the toxicity and defined the control measures for the safe large-scale use of the explosive. Obviously, this method affords important economies both in the installation of processes and in the prevention of disability.

Governmental industrial hygienists may well anticipate in the post-war period, if not before, the added responsibility of occupational disease and accident control in agriculture. Although some work has been done on the health and safety problems of agricultural workers, the field remains virtually untouched. Should these workers be

brought under the provisions of the Social Security Act, a further expansion of state and local industrial hygiene services will be essential.

We have not yet considered the means with which we are to meet the post-war problems of industrial hygiene. This is a problem in itself. First in importance is the dearth of professional and technical personnel. The specialty of industrial hygiene had scant attention in our medical and engineering schools before the war. Postgraduate training in the professions has already suffered more than we realize as a result of war. One of the most serious responsibilities facing us today is the training of young physicians and engineers who have gone directly from school to the armed forces and who are not prepared to give industrial hygiene the transfusion of new blood it must have. Although some postgraduate training of nurses is being done, the vast majority of the young women now being trained in the U. S. Cadet Nurse Corps will go into bedside nursing. Their absorption into public health and industrial nursing after the war depends upon our ability to give them the training essential in these specialties.

The training of other professional personnel, technicians, and sub-professional workers for industrial hygiene service offers a similar challenge. There will be many competent young men and women returning from our armed forces who are accustomed to the development of skills and to discipline. We should begin now to plan intensive training in industrial hygiene, not only for the physicians, engineers, chemists, and nurses, but also for the technicians and other personnel who will be needed.

It is not too soon for official and nonofficial industrial hygiene services to approach the educational institutions with a view to the establishment of training facilities. Under the pro-

visions of Title VI of the Social Security Act, the U. S. Public Health Service before the war developed with numerous universities a program for the public health training of state personnel. Due to the lack of educational facilities, little specific training in industrial hygiene could be done. When the war is over, we should be in a position to write a strong industrial hygiene education plan into the public health training program. The establishment of new facilities in existing schools of engineering and medicine would not only service personnel of official agencies but would attract students destined for employment in industry.

FINANCING INDUSTRIAL HEALTH SERVICES

Those industries which have established adequate in-plant health and safety services, I am confident, will continue and even expand the facilities as needed. It is in such plants that we find the practical demonstration of the best that industrial hygiene has to offer. This group is still woefully small, a microcosm in an industrial establishment so large that it already staggers the imagination!

The large group of small plants in the United States probably cannot afford individual in-plant services, but can undoubtedly be interested in any practical plan for the joint utilization of a central community industrial health and safety service. The majority of plants in all size groups, however, do not have in-plant services and appear content with perfunctory compliance with the minimum requirements of workmen's compensation laws.

Nevertheless, a good proportion of the industrial establishments in this country, and the labor unions, too, have learned more about industrial hygiene in the past two years than they ever knew before. Management and labor, then, are the sources from

which demands for more services will come, and I am sure the demand will continue—in crescendo.

I do think, however, that any substantial real expansion of industrial hygiene work in the future depends upon certain eventualities. First, if management, labor, and the government acquire a larger financial stake in workers' health and safety, obviously increased facilities will be demanded, both within the plant and in consultant and technical services. There is now before the Congress legislation which would provide health insurance for workers covered under the Social Security Act. If this or similar legislation is passed, the three contributors to the insurance plan will insist upon adequate preventive services to reduce time loss due to disability.

Further legislative action with respect to the health and safety of industrial workers should be on the post-war agenda of the states, management, and labor. Legislation requiring minimum safeguards against occupational hazards is still inadequate in certain states. The inspection forces are not sufficient to detect every case of non-compliance with existing laws. In order to equalize the hazards to workers and the costs to industry throughout the country, adequate legislation and adequate services are essential in every state.

-Another factor contingent to the expansion of industrial hygiene is the participation of state and local governments. Have they been participating enough? The record is clear. For the fiscal year 1943-1944, state and local industrial hygiene services have budgeted \$1,225,000 from all sources. Of this total, 49.8 per cent is in federal funds. An additional \$209,000 was budgeted in salaries of personnel loaned by the Public Health Service under the Emergency Health and Sanitation Appropriation. Thirty-five state health

departments contributed a little over one-fourth, or 27 per cent. Two state departments of labor budgeted 13 per cent of the total, and 10 local health departments contributed slightly over 10 per cent.

Industrial hygiene services in 7 states are financed this year entirely by federal funds, and 8 others receive from three-fourths to over 90 per cent of their funds from the same source. Thirteen other units derive from one-half to three-fourths of their budgets from federal funds. Thus, in 60 per cent of the 47 existing governmental industrial hygiene services, the major cost is borne by the federal government. It should be said, in all fairness, that this record is a considerable improvement over that in the years immediately following the passage of the Social Security Act, or even over that of last year.

These expenditures are all exclusive of salaries of Public Health Service personnel assigned to state units under the Emergency Health and Sanitation Appropriation, as already stated. However, we must not lose sight of the fact that the Emergency Health and Sanitation program is limited by the duration of the war and 6 months thereafter. It is important, therefore, that the states include in their post-war plans the taking up of this deficit.

These facts make clear the pitifully small effort for the health and safety of our industrial population both before and during the war. No one thinks for a moment that American industry will be reduced to its pre-war stature even after the post-war transition to consumer production. Certainly, the future promises a period of industrial activity greater than at any time in the ten years preceding the war. Some of the nation's most influential industrialists have stated frankly that the present and future problems of production are not in engineering

and operations, but are human problems—how to increase the efficiency and promote the well-being of the men and women whose stake in modern industry is their labor. The provision of adequate health and safety services is the first step toward realizing that goal.

The service rendered by state and local industrial hygiene units is the spear-head for the future advance of industrial hygiene. I will go further. It is the spear-head for the future advance of public health. Aside from the need for specialized services in the control of occupational diseases and accidents, the industrial hygiene program offers the channel for the ultimate control of such long-fought diseases of public health importance as tuberculosis and venereal disease; for the advancement of public health dentistry; and adult hygiene in general.

Governmental industrial hygienists at every level are well aware that state and local governments are not meeting their industrial hygiene responsibilities. Lack of funds has often been given as an excuse. But is it not possible that a little thought, a little better planning of budgets, and a real effort to inform local health officers and appropriating bodies might bring to light enough money and enough elbow-grease to strengthen industrial hygiene services?

There are no non-industrial states in the United States. The war has industrialized many areas hitherto entirely rural. Yet, 10 states still have no industrial hygiene services whatsoever.

The present minimum staffs in the 38 states having such services must be strengthened, and because of the wide dispersion of industry it is desirable to decentralize services in industrial hygiene at district, city, and county health department levels.

These are important pieces of unfinished business which the public health movement must complete, either now or after the war. Failure to do

so will mean that public health has missed its great chance to serve as a leader in the promotion of national well-being.

INTERNATIONAL RELATIONS IN INDUSTRIAL HYGIENE

After the war, the reconstruction of occupied territories, the transition from war production to a peace economy in the United Nations, and the expansion of industry in backward countries will present innumerable industrial hygiene problems best solved by an interchange of knowledge and skills. Any plans for post-war rehabilitation should include plans for industrial health and safety. The industrial hygi-

enist should be given the same responsibility in national and international programs for the promotion of workers' health as has been given to public health and medicine in the United Nations' plan for the improvement of human nutrition.

Industrial hygiene in the post-war world has a magnificent opportunity to advance human health and welfare through the application of the knowledge and experience gained during the war. Those of us who have shared that experience should begin now to project our thoughts into the future and consider how best we can serve in the post-war world—for it will be a world of work.

Proposed Report on the Educational Qualifications of Medical Administrators of Specialized Health Activities*

Considered in This Report Are the Following Specialized Activities:
Maternal and Child Health, Control of Tuberculosis, Venereal Disease, Cancer, Mental Hygiene, and Industrial Hygiene.

AMONG essential health services are specialized activities, that is, activities designed for the control of individual diseases or groups of diseases, and for safeguarding and promoting the health of selected population groups. All such activities are concerned with the large scale application of highly technical medical knowledge; all of them include the continuous observation of many individuals over long periods of time, and all of them require the use of numerous facilities in the health agency and elsewhere in the community. Each specialized activity calls for a medical administrator who is a physician qualified both in his particular line of work and in the general field of health administration. For many years maternal and child health programs and services for the control of tuberculosis, syphilis and other venereal diseases have been organized as separate units in health agencies of any considerable size. Specialized activities more recently organized similarly include those for in-

dustrial hygiene, mental hygiene, and the control of cancer, and it is to be expected that additional new undertakings will be placed in the same category. Duties and functions, and educational and personal qualifications common to medical administrators of all specialized activities will first be presented in this report, followed by a summary of desirable postgraduate clinical training and experience in each field.

The duties of the medical administrator who serves under the general direction of the health officer include participation in clinical activities to a greater or lesser degree depending upon the size of his medical staff. Even in large organizations, he serves as a consultant, and in smaller agencies he serves as a clinician and takes part in diagnostic and treatment activities. He also is responsible for securing the coöperation and assistance of the medical profession and for judging the effectiveness of clinical procedures in force and the efficiency with which they are carried out. The medical administrator is responsible for changing clinical and other activities so that they comply with the best modern practice, and he must be capable of taking advantage of new discoveries of public health importance. He has opportunity for research of his own and of inaugurating special studies and research for the members of his staff.

* The Committee on Professional Education of the American Public Health Association publishes this report before transmittal to the Governing Council in order to permit the members and Fellows of the Association to review it and to offer criticisms and suggestions in the further consideration of the report. It would particularly welcome suggestions as to the amplification of the various specialties included in the report.

This report, like all other statements of the committee on professional and technical qualifications in public health, is subject to periodic revision in order that it may be kept abreast of the best thought.

Specialized health activities all require the establishment and maintenance of systems of reporting and of registers for keeping patients and their associates, and other classes of individuals under continuous observation. The medical administrator's duties include supervision of those record systems and responsibility for the character and quality of data collected in them. Such data largely result from clinic and field services. Most important among the latter are services rendered by public health nurses. It is the duty of the administrative officer to formulate definite policies for home visiting and other public health nursing activities in his field. Control measures for diseases under the heading of special activities and for promoting the health of selected population groups are by no means limited to those administered by the director of a given activity. The medical administrator uses numerous health department facilities, such as laboratory services, those in health education, in environmental sanitation, and in special activities other than his own. His duties include a thorough understanding of related work done by other agencies, official and voluntary, and he may advise or assist in programs besides those in the health agency to which he belongs.

The staff of units for special activities in large organizations usually includes several physicians, and there may be a number of full-time positions under such titles as assistant director and clinical consultant. Natural lines of promotion are from those subordinate positions to that of medical administrator. Qualified physicians with full-time administrative experience in smaller agencies are to be considered eligible for higher grades of positions in larger organizations. Part-time physicians are frequently employed in specialized activities to serve in clinics and for other technical purposes. As a rule these

physicians have few, if any, administrative duties, and are not to be regarded as qualified for medical administrative positions until they have had the necessary public health training and experience.

PERSONAL QUALITIES

The medical administrator of specialized activities should have the same personal qualities that make for success in other administrative positions. He should, in brief, possess such personal characteristics as adaptability, common sense, creative ability, good health, judgment, leadership, and pleasing personal appearance.

EDUCATIONAL BACKGROUND

Basic educational qualifications for medical administrators of specialized activities are the following:

1. Fundamental training in the sciences and humanities at least equivalent to that required for a college degree in the arts and sciences
2. Completion of a course leading to the degree of Doctor of Medicine in an approved medical school
3. Internship of at least one year in an approved general hospital
4. Eligibility to examination for medical licensure in the state where service is to be rendered

GRADUATE TRAINING AND EXPERIENCE

Graduate clinical training and experience in each special activity under discussion are summarized below. Practical considerations sometimes demand that graduate training in the special activity be combined with training in public health. The following statement takes this fact into account, but it is preferable for the medical administrator to have the requisite amount of clinical training before enrollment in a public health course.

1. Completion of a program of study¹ of not less than one full academic year in a university leading to a degree in public health.

Such a program should cover the general field of public health: administration, biostatistics, environmental sanitation, epidemiology, health education, laboratory methods, public health nursing, and should be accompanied by special instruction in the application of the basic principles learned to the functions and duties of the medical administrator's special activity, and, if necessary, instruction in the clinical features of the activity.

2. Experience in general administration or in a subordinate position is desirable for all medical administrative positions.

REFERENCE

1. See "Memorandum Regarding Minimum Educational Facilities for the Postgraduate Education of Those Seeking Careers in Public Health," prepared by the Committee on Professional Education, American Public Health Association and published in the *American Journal of Public Health*, May, 1942.

SUMMARY OF GRADUATE TRAINING AND EXPERIENCE IN SPECIALIZED HEALTH ACTIVITIES

The following summaries present desirable graduate training and experience for career service in the administration of specialized activities. Recognition is given to the fact that long clinical experience and distinguished service in the special field may take the place of formal training in an institution or hospital.

MATERNAL AND CHILD HEALTH

Two years of graduate training in pediatrics or obstetrics or both; part of the candidate's experience should preferably be in the administration of a program under supervision.

TUBERCULOSIS

Two years' graduate training in tuberculosis in an approved tuberculosis sanatorium or hospital, or equivalent training in an outpatient service; part of the candidate's subsequent experience should be in the administration of a tuberculosis program.

VENEREAL DISEASE

Two years' graduate training in the diagnosis and treatment of venereal diseases in an approved hospital, or outpatient service; part of the candidate's subsequent experience should be in the administration of a venereal disease program.

CANCER CONTROL

Two years' graduate training in the diagnosis and treatment of cancer, including training in the pathology of the disease.

MENTAL HYGIENE

Two years' graduate training in psychiatry in an approved mental hospital, and one year's experience in outpatient work with children in a clinic employing the integrated services of psychiatrist, psychologist, and psychiatric social worker. Desirable supplemental experience includes clinical neurology, service in institutions for epileptics, mental delinquents, and defectives, and neuropathology.

INDUSTRIAL HYGIENE

Clinical graduate training for medical administrators in industrial hygiene may be in the field of industrial toxicology and in the diagnosis and treatment of occupational diseases. The medical administrator should have good knowledge of physiologic problems, and he should be trained to serve in directing rehabilitation services for the handicapped and in the technics of accident prevention and safety. Training and experience are best secured by service in an industrial plant.

The Cuban Government Honors General Simmons

On May 17, at the invitation of the Cuban Government and Dr. Alberto Recio, the Minister of Health, Brigadier General James Stevens Simmons, Chief, Preventive Medicine Service, Office of the Surgeon General, U. S. Army, visited Havana and took part in the dedication of the new National Institute of Health. During the ceremonies President Batista decorated General Simmons with the Medal of the Carlos J. Finlay National Order of Merit in the grade of *Gran Oficial*.

The President also sent by General Simmons to Major General Norman T. Kirk, the Surgeon General of the Army, a certificate conferring the Carlos J. Finlay Order of Merit in the grade of *Gran Cruz* on the former American Yellow Fever Commission for its fundamental experimental work in Cuba on the etiology and transmission of yellow fever under the leadership of Major Walter Reed. The certificate will be preserved in the Army Medical Library in Washington.

A Fly-borne Bacillary Dysentery Epidemic in a Large Military Organization*

COLONEL DWIGHT M. KUHNS, M.C., F.A.P.H.A., AND
FIRST LIEUTENANT THEODORE G. ANDERSON, SN.C.

*United States Army, Fort McPherson, Ga.; and Army of the United States,
Fort McPherson, Ga.*

THE purpose of this paper is to report a massive epidemic of bacillary dysentery in which the same specific pathogenic organism was isolated from both flies and dysentery cases. The outbreak occurred in a large military unit which was in bivouac in one of our southern Army camps. Clinically, the dysentery was typical but of short duration. The average duration of the disease in ambulant cases was 2 days and the average hospital stay of the more severe cases was 7 days. Although this might indicate that the type of dysentery was not severe, there was considerable weakness and disability following the disease. A decisive part of a Division was thus incapacitated in this particular outbreak of 1,557 cases of clinical dysentery. Three hundred and eighty-three of the cases were bacteriologically positive. The causative organism, in 91 per cent of those found positive, was serologically and biochemically identified as *Shigella paradysenteriae*, Boyd 88. Figure 1 shows the incidence of cases and the number of stools found bacteriologically positive. This incidence was determined by taking a brief history of all individuals in the entire Division

who stated that they were having or had had the disease. The number of those found to have positive cultures was determined by culturing, after September 25, 1942, all individuals with a history of having had the disease while in bivouac at this site. Figure 1 indicates that the incidence of dysentery began to increase about two weeks after the Division had been in bivouac in this area. There was no history of the presence of flies prior to the occupation of this area by the Division. About September 1, flies began to appear in numbers which became larger as the intensity of the epidemic increased. The decrease in case incidence was accompanied by a decrease in fly incidence. The latter was partially due to the enforcement of strict fly control measures and to the appearance of cool weather.

SANITARY SURVEY

A general sanitary survey showed a marked deviation from the usual enforcement of the well known sanitary protective measures. These difficulties arose in part because the stay of this unit in the bivouac area, which was originally supposed to be of short duration, was extended into weeks by exigencies of the Service. The survey showed that water, ice, and milk were satisfactory. The progressive, rather than abrupt, nature of the outbreak and

* Presented at a Joint Session of the Epidemiology, Health Officers, Maternal and Child Health, and Laboratory Sections of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 14, 1943.

FIGURE 1—Cases of Dysentery, X-Division, X-Camp, 1942 (According to date of onset as given in individual history records)

the simultaneous occurrence of the disease in all parts of the entire area indicated that the means of transmission of the infection was not food handlers.¹ However, a lack of proper operation of latrines permitted direct fly contact with human excreta. The open, straddle trench type latrines were in use but were being replaced by the enclosed box type. Excreta in some of the remaining straddle trenches was uncovered and accessible to flies. Flies were found breeding in the old closed latrines of units previously bivouacked in the area. Innumerable flies were everywhere. Inadequate protection of messes against flies afforded opportunity for the direct contamination of foodstuffs during preparation.^{2, 3} These conditions, aided by latrine flooding that disseminated fecal material to greater fly contact, apparently were factors in precipitating the epidemic.^{4, 5}

After an increased number of dysentery cases began to appear, steps were immediately taken to eradicate the flies and to improve general conditions of sanitation and food protection. By the latter part of October, there was a general enforcement of all sanitary

measures which resulted in a marked reduction of the fly population.

It is interesting to note that dysentery abruptly stopped in one unit when it was sent from the bivourac area for training purposes to an area relatively free from flies.

METHODS AND MATERIALS

Due to the military situation, it was desirable to know something of the extent and type of infectious organisms present in the organization, as well as to investigate the possibility of confirming the rôle of the fly as the transmitting vector.^{5, 7, 8} Therefore, a mobile laboratory and staff were sent to the site of the epidemic in order to study the outbreak at its origin.

A rectal swab culture survey was made of all individuals in the Division who were having or gave a history of having had the disease and of all permanent food handlers. In addition, the state of infectivity of the Division was analyzed by *selecting and culturing* one entire company as a sample. Flies were cultured from various sources, which will be shown later.

The Hardy⁹ rectal swab method was

TABLE 1

Results of Swab Cultures from All Men in the Division With History of Diarrhea During Epidemic Period

	Days from Recovery to Culture	Number of Cases	Positive for <i>Shigella</i>	
			No.	Per cent
Men with history of diarrhea	Current	366	161	43.9

used for collecting specimens from all individuals cultured in this investigation. The swab collected by this method was placed into Selenite-F broth (Balt. Biol. Co.) and incubated at 37° C. from 12 to 16 hours. At the end of the incubation period, plates of Salmonella-Shigella (Difco) media were streaked directly from the Selenite-F tubes. All plates were incubated for 24 hours at 37° C., when several clear colonies were picked and inoculated into Kligler Iron (Difco) slants. All typical *Shigella* growths, after 24 hours' incubation at 37° C. on Kligler Iron, were checked biochemically and serologically. The serological confirmations were made by spot ag-

glutinations, using a 1:10 dilution of the specific *Shigella* antiserum. For specific polyvalent (V, W, X, Y, Z) differentiation and for confirmation of the specific types, *Shigella paradysenteriae*, Boyd 88, *Sh. sonnei*, and the other species isolated, macroscopic serial dilution agglutination tests were conducted.

Flies collected in fly traps were triturated and cultured in lots of 15 in the same manner as that described for the rectal swabs.

RESULTS OF BACTERIOLOGICAL OBSERVATIONS

NOTE: Six of the cases yielding Boyd 88 were complicated with one of the other *Shigella paradysenteriae* strains but were included under Boyd 88 because this strain was the predominating one.

Cultures were taken from 1,557 men in the Division who had diarrhea or who gave a history of having had diarrhea during this outbreak. The number found to be positive for *Shigella* was 383, or 24.6 per cent, as shown in Table 1. It is interesting to note from the table that 28 days after the infection 12.8 per cent of the individuals cultured were still positive for *Shigella* organisms. The predominating organism was *Shigella paradyserteriae*, Boyd 88, which represented 91.6 per cent of the pathogens. Other organisms present were *Sh. sonnei*, *Sh. paradyserteriae*, "X", *Sh. alkaescens*, and *Sh. dispar*. (Table 2).

Rectal Swab Cultures from Food Handlers—Due to the fact that the disease was widespread, it was believed

that a large number of food handlers were infected and thus might contribute to the continuation of the epidemic. Therefore, all permanent food handlers were cultured to determine those carrying the organisms. Positive rectal swab cultures were obtained from 58 of the 528 food handlers (see Table 3).

This group actually constituted a sample of 528 men chosen at random from the entire Division. When divided according to the presence or absence of a history of diarrhea, it was found that 10 (12.0 per cent) of 85 food handlers with a history of diarrhea were positive, whereas 48 (10.8 per cent) of 443 without such a history were positive. These results demonstrate that in this epidemic the

presence of the carrier state was independent of a history of diarrhea, and indicate that subclinical infection was widespread.

Rectal Swab Cultures from One Entire Company—A representative sample of the Division, consisting of one company (143 men), was cultured. The number of men who gave a history of having had diarrhea was 32; of these, 9, or 28.1 per cent, yielded positive cultures. Of those who gave no history of diarrhea, the percentage found positive was 20.7. Of the entire company, 22.4 per cent were found to be carriers of *Shigella* organisms (Table 4).

the flies from the closed latrines, when cultured, were found positive for pathogenic organisms.

SPECIAL CONTROL MEASURES

Elimination of Flies—In addition to the sanitary control measures already in force, special measures were taken to bring the fly breeding under control: (1) The covering of the old latrines with heavy paper, which was packed down by 3–4 inches of oiled sand, was effective in preventing egress of fly larvae. (2) The straddle trench type of latrine was supplanted by the deep pit type, covered by fly-proof boxes. (3) Trained orderlies were

* Each batch contained 15 flies

† All lots negative for pathogens, but positive for *E. coli*, *Paracolon*, and *Protus*

Cultures of Flies Collected in Representative Mess Areas, Latrine Areas, and Post Exchanges in the Entire Bivouac Area—In the first 2 weeks of October (during the decline of the epidemic), 292 different lots of flies were collected from sources as outlined in Table 5.

Each lot consisted of approximately 15 flies. These were identified as the common housefly, *Musca domestica*. Of the 292 lots, 9, or 3.08 per cent, yielded *Shigella paradysenteriae*, Boyd 88. Five of these positive lots came from field mess areas and 4 from latrines in active use. One of the most significant findings in the fly culturing study was that, although flies were breeding in great abundance, none of

placed on duty to maintain the proper oiling, fly-proofing, and upkeep of the latrines. (4) Attention was directed to the training of soldiers to utilize the latrines.

Protection of Food from Flies—The screening of messes was instituted to protect food while being prepared. Flies in the messes were eliminated by swatting, spraying, and the use of fly paper and fly traps.

Elimination of Sources of Infection—An attempt was made to eliminate the sources of infection in the usual manner by the early detection and isolation of cases. In addition, a study was made to evaluate sulfasuxidine*

* Sulfasuxidine given as prescribed by Sharp & Dohme.

and sulfaguanidine* in the treatment of carriers in the field. One hundred and twelve positive convalescents were given sulfaguanidine, 132 sulfasuxidine, and 60 remained as untreated controls. Cultures were taken on all cases at weekly intervals for 3 weeks. Negative cultures were obtained at all times after treatment with either sulfonamide, whereas the controls remained positive in approximately the same percentage as shown in previous tables. Thus, either drug appeared to be effective in relieving the carrier state.

SUMMARY

The following is a summary of the findings of this investigation:

1. A large outbreak of 1,557 cases of bacillary dysentery occurred in which *Sh. paradysenteriae*, Boyd 88, was found in 91.6 per cent of the organisms isolated.

2. The onset of the epidemic was about 2 weeks after troops had moved into a bivouac area in which flies had begun to breed in large numbers because of improperly operated straddle trench latrines.

3. The epidemic was gradual in onset, widespread in distribution, reached its peak in about 2 weeks, and declined simultaneously with the gradual disappearance of flies.

4. The predominating organism isolated from the dysentery cases, *Sh. paradysenteriae*, Boyd 88, was cultured from 9 lots of flies collected in the kitchens and operating latrines.

5. In one unit sent away from the bivouac area for training, no further cases of dysentery occurred after 48 hours.

6. The rate of asymptomatic infections or carriers in 443 food handlers was 10.8 per cent. This would appear to indicate that a state of immunity does exist against the causative organism for the disease.

7. The importance of the common housefly in the transmission of bacillary dysentery should be stressed more than it has been in

the past, and corresponding attention should be directed to its control.

NOTE

It is desired to express appreciation for assistance in this problem to Colonel S. W. French, M.C., Colonel Charles G. Souder, M.C., Brig. General Henry C. Coburn, Jr., M.C., Lieutenant-Colonel Harry E. Wright, M.C., Captain Norman L. Cressy, M.C., Captain L. Roland Kuhn, Sn.C., Captain Carl T. Nelson, M.C., Captain Harry A. Feldman, M.C., U. S. Army, and Hortense E. Garver, P-1, Junior Bacteriologist, Fourth Service Command Laboratory; Members of the Subcommittee on Dysentery, Commission on Tropical Diseases, Board for the Investigation and Control of Influenza and Other Epidemic Diseases in the Army; Dr. Carl TenBroeck, Director, Dr. John B. Nelson, and Dr. Frederick Bang, Jr., Rockefeller Institute for Medical Research, Princeton, N. J. Appreciation is also expressed for special technical assistance to Frances C. Sterne, SP-5, Medical Technician, and Marguerite Jane Barnes, SP-4, Assistant Medical Technician, Fourth Service Command Laboratory, and other members of the Fourth Service Command Laboratory Staff.

Appreciation is further expressed to Brig. General James S. Simmons, M.C., Colonel Stanhope Bayne-Jones, M.C., Preventive Medicine Section, Office of The Surgeon General, U. S. Army, Washington, D. C., and Colonel George R. Callender, Director, Army Medical School, Washington, D. C., and to Major Jerome S. Harris, M.C., and First Lieutenant Dewitt F. Mullins, Jr., M.C., Fourth Service Command Laboratory, for their assistance in assembling and compiling this material.

PHYSICIAN, POLICEMAN, OR PEDAGOGUE?

WITH the elimination of water supplies and milk supplies as causes of large-scale community epidemics, the control of food handling in the store and the restaurant has become the most important factor in the control of alimentary infections in most American cities. The return from African and South Pacific service of hundreds of thousands of carriers of the germs of amebic and bacillary dysentery will make this problem one of major significance in the next few years.

There are three different correlated approaches to the control of food-borne infections. The first of these is the medical approach, the attempt to eliminate sources of possible infection by routine health examinations of food handlers. This procedure has serious limitations in the opinion of thoughtful health administrators. The infectivity of individuals varies from week to week and from day to day; and no system of examination can protect against the transient positive throat culture or the temporary staphylococcus infection on the finger. Routine health examinations have been defended by some as aids in the general community program for finding cases of syphilis and tuberculosis. The place to find new cases of syphilis and tuberculosis, is, however, among the contacts of known cases; and routine examination of random population groups has been rightly described as "a slipshod substitute for intelligent epidemiology." It may well be desirable to insist on stool examinations for servicemen returning from the tropics who desire to serve as food handlers. As a general basis for the control of food-borne disease, however, medical supervision is not the answer.

A second approach to the solution of this problem is to be found in law enforcement. This is obviously an essential part of the program. Codes of cleanliness for food handling establishments, licensing of such establishments, regular and conscientious inspection service, must be available for effective control. Yet all this is not enough. The policeman, like the physician, can only visit a given restaurant at relatively infrequent intervals; and much may happen between visits.

What we really need for effective control is an inspector on the ground every

day and every hour of the day; and to approximate such an ideal we must invoke the forces of education. No proprietor or responsible administrator desires the scandal of an epidemic among his customers. There is no real diversity of interests here, only the need for enlightenment and motivation. The major purpose of each inspector's visit should be the enlistment of informal deputies on the spot who can note deviations from sanitary practice in the day's routine—who can detect the waiter with a cough, the pastry cook with an infected finger. The Memphis food handlers' school¹ which, through an eight day course of instruction (conducted with the coöperation of the local Restaurant Association and Chamber of Commerce), reached 25 per cent of all food-handlers in the city, and the school at Miami, conducted by the Dade County Health Department² are excellent examples of progressive public health control. By the aid of such special devices and by making every contact of the physician and the sanitary inspector primarily an educational contact, our program of food sanitation can be made truly effective.

THE HEALTH COUNCIL AND ITS POSSIBILITIES

THE building of sound health programs for our local communities is too important to permit of any waste of effort or duplication. Every city of any size has a multiplicity of groups concerned with one or another phase of public health—official health departments, private health agencies, clinics, hospitals, and professional organizations of physicians, dentists, and nurses. Working together in a health council with full understanding of each other's programs, they can attain maximum results with limited staffs and funds. Such a council can serve as a forum for discussion of health problems, a medium for continuing analysis of community needs and for stimulating ways of meeting them, a means for avoiding duplication and friction, machinery through which citizen participation can be made effective, and sound community health programs can be formulated and kept up to date.

When competently directed, the health council has proved its worth. Operating, usually, as a division of the Community Chest or Council of Social Agencies, the council functions most effectively when it has a considerable measure of autonomy, its own paid staff, and a reasonable budget. Without these, it has little chance of success in any sizeable city. With them, it can be an effective ally of the official department and a strong unifying force for promoting public health.

When Dr. Haven Emerson made a critical analysis of the Cincinnati Public Health Federation at its own request several years ago, he termed it the "Community's Conscience in Health Matters." Having the confidence of the Health Departments of the City and County, the faculty of the College of Medicine, the Academy of Medicine, the Dental Society, the Graduate Nurses' Association, and the backing of the Community Chest, this Federation has admirably demonstrated the effectiveness of sound coördination.

All health agencies, public and private, and the appropriate professional

organizations, as well as social and civic agencies with a direct interest in public health, are represented in the Federation's delegate body. This group elects the officers and twenty-five members at large who, with the health commissioners of the City and County and the chairmen of the thirteen councils, make up a Coördinating Committee—the active governing body of the Federation. The 500 citizens, who participate in the Federation's work as delegates or members of one or another of its thirteen councils, constitute its greatest strength.

Each of the Federation's Councils is made up of organizations and individuals active in its particular field, and develops its own program subject to the approval of the Coördinating Committee. Ten of the Councils—Cancer Control, Child Hygiene, Clinics, Diabetes, Health Education, Heart, Mental Hygiene, Mouth Hygiene, Community Nursing, Nutrition—were organized as divisions of the Federation. Their activities consist primarily of coördination, education, and programming. The Anti-Tuberculosis League, the Better Housing League, and the Social Hygiene Society have been recognized as the Federation's Councils in those fields.

The Federation has fought consistently to strengthen the official Health Departments which it considers the most important cog in the community's public health machinery; it has initiated and stimulated and coördinated programs for cancer control, diabetes, heart disease, enteritis, and appendicitis; through the joint efforts of diet specialists, it has carried on an effective nutrition program; it has organized a sizeable and effective Negro health clinic where Negro doctors and dentists had their first local opportunity for participation in clinic work; it has launched a strong centralized mental hygiene clinic; it has been influential in having a children's orphanage transformed into a much needed children's convalescent home.

Coöperating with the Anti-Tuberculosis League, the Federation secured a \$2,000,000 bond issue which built the County's modern Tuberculosis Hospital. It conducted, through a special Citizens' Committee, a successful bond issue campaign for \$3,500,000 to construct a new County Home and Chronic Disease Hospital which is in the blue print stage ready for building as soon as the war ends. It likewise conducted a \$1,500,000 bond issue campaign which will result in important improvements in the City's General Hospital when critical materials become available.

The Cincinnati organization maintains continuing studies of resident mortality by age, sex, and race groups, and makes a comparative analysis of mortality in thirteen comparable American cities. The first published report of these studies for three years, 1929–1931, was widely publicized and led to notable changes of emphasis in the local health program. Similar studies for the period, 1939 through 1941, are being completed and will be published within the next few months.

Due to its recommendations, some local health agencies have voluntarily modified their activities, others are making changes, and two have transferred their work to tax support.

A good example of teamwork is a program of health education sponsored jointly by the Health Department, the Academy of Medicine, and the Federation. The program consists of car cards in buses and street cars, a series of monthly posters in factories, several regular radio programs, daily or weekly health series in two of the large dailies and in suburban papers, exhibits, monthly bulletins for Parent-Teacher Associations, and periodical nutrition bulletins for

families of low income. The health messages prepared and distributed in a single year would fill eight or ten fair-sized books. Health education is an especially logical activity for a health council because its scope embraces the whole field from dental to mental health and because official departments usually find it difficult to secure funds for effective education and publicity.

Concentrating its efforts on health problems related to the war, the Federation initiated a Consultation Service for men rejected at the local Induction Center and is now conducting psychiatric screening of registrants in coöperation with Selective Service. It has played an important rôle in the effort to reduce unnecessary demands upon physicians and nurses and in promoting enrollment in schools of nursing.

The Federation's work is financed principally from Community Chest appropriations. Its staff consists of an Executive Secretary who is also the Head of the Better Housing League, an Associate Secretary (a physician who serves also as Director of Research), a Health Education Assistant, and two volunteers. One of the volunteers gives full time and does a remarkably efficient job as Assistant Secretary. The other volunteer, who devotes most of his time to the work, is a distinguished authority on advertising technics and is the Federation's President.

Cincinnati is cited as an example because it has one of the oldest of such coördinating health agencies. Other leading Councils, such as those in Cleveland, Boston, Louisville, Chicago, or Philadelphia, would have served as well. Health councils are now functioning in about fifty cities. Unfortunately, many of them are weak and ineffective because they lack funds and leadership. There is no magic in the word "health council." Only if such a council has vigorous, intelligent direction and financial backing can it develop effective teamwork in the health field.

Medicine and the allied sciences have given us powerful tools for health building, of which no community is making the fullest use. The health council is one means by which citizens and community health forces can unite to make such tools effective.

EVALUATION OF CLINIC NURSING SERVICE

THE health administrator should be keenly interested in the intensive survey of Public Health Nursing Services in Clinics sponsored by the N.O.P.H.N. Committee on Nursing Administration. This study covered 212 clinics and health conferences of various types (child health, crippled children, maternity, tuberculosis, and venereal disease) in 38 states—a very representative sample. As a basis for the survey, lists were drawn up of 27 activities which might be performed in preparation for the actual clinic session, 105 activities which might be performed during the session, and 15 activities which might be performed after the session. The lists of these activities were then submitted to a jury of public health administrators, physicians, and public health nurses for the selection of those functions which should be performed by the public health nurse and in this way two pre-clinic, seven clinic, and four post-clinic activities (with other functions in certain special types of clinics) were defined as among the primary tasks of the public health nurse. This standard was then checked against actual practice in the 212 clinics studied.

The basic duties so selected were chiefly concerned with two fundamental functions—direct personal contact with the patient and health education. These are the two things which only the trained public health nurse can most effectively accomplish. They differ of course with different types of clinics. In the case of child health there were 18 public health nursing functions, 14 of which were actually performed by nurses in 50 per cent of the clinics studied. In the case of crippled children's clinics, only 7 out of 16 functions were actually performed by public health nurses in 50 per cent of the clinics. Maternity clinics showed 9 out of 13 functions so performed; tuberculosis clinics, 10 out of 15; venereal disease clinics, 6 out of 16. Clearly many tasks which should be accomplished by the public health nurse are either not being performed at all or are being delegated to less competent personnel.

On the other hand, the nurses in these clinics are devoting much of their time to many other activities not accepted as essential public health nursing functions—to duties such as preparing examining tables, distributing and caring for linen, recording weights, making out reports, and cleaning up equipment, which could quite as well be performed by nurses without public health training or by volunteers or paid assistants.

Assuming—as we must—that the primary purpose of the health clinic or conference is an educational one, it is clear that the practices revealed by this study not only represent a serious waste of professional time but also involve failure to attain maximum results from the procedure as a whole. It is the responsibility of the public health administrator, first, to secure well qualified public health nurses (only 32 per cent of those found functioning in the present study had completed a special program of study in public health nursing and only 53 per cent had had prior public health experience); and, second, to organize the service so as to use appropriate personnel for each particular task.

We have only touched on the highlights of this N.O.P.H.N. report, which contains not only analysis of various clinic functions but very suggestive time-study data. The entire report should be read to obtain its full value.¹ Above all, health officers and directors of nonofficial health agencies would do well to obtain from the N.O.P.H.N. copies of the appraisal schedule used and to evaluate the organization of the clinics and conferences for which they are responsible by the excellent procedure here developed.

Industrial Sanitation

Engineering Section

IT is universally realized that war production is the very core of our nation's offensive action, and will remain a paramount duty until the war ends. Experience during the first year and a half of war has clearly shown that the worker himself is the most important factor in getting out production. Since we have practically reached the limit in the size of our labor force, we are therefore faced with the increased necessity of effectively utilizing and conserving all of our man power resources. Industrial hygiene services have a major part of the responsibility in meeting this challenge by assisting industries in the prevention of illnesses and deaths from industrial poisons, and in the maintenance of physical fitness of all workers. It goes without saying that in the field of industrial hygiene the engineer has a major contribution to make.

Estimates made by the War Manpower Commission show that of a total labor force of nearly 63,000,000 persons (including the armed forces), something like 38,000,000, or 60 per cent, are in the armed forces or engaged in activities essential to the war. Aside from the large numbers involved, the industrial hygienist's task has been made even greater by the fact that the labor force itself has changed materially. This tremendous change in the make-up of the working force is of utmost significance, both in military service and in war pro-

duction for even these largest consumers of man power are employing women, adolescent boys, the aged, and the handicapped. Furthermore, when we speak of man power today we inevitably must include all of us—the professional and technical personnel responsible for production and for health and safety; the supervisory personnel; the workers themselves. This altered labor force, the speed-up associated with production, longer hours of work, and the increase in exposure to many hazardous materials and conditions, have all augmented the task of the industrial hygienist. Furthermore, because the industrial hygienist has done a good job in the field of occupational disease control, he has had thrust upon him more problems, not only in number, but also in variety. Unfortunately, the task force in industrial hygiene has not materially increased for handling these greatly increased responsibilities.

Prior to the war considerable progress had been made in the establishment of industrial hygiene services throughout industry, and in official and nonofficial agencies. Large industrial establishments had begun to employ physicians, engineers, and chemists for specific work in the field of preventive medicine. Nonofficial agencies, such as insurance companies, universities, and foundations, had also established industrial hygiene services. Perhaps the greatest impetus to industrial hygiene in official agencies was given by the

federal government when it began to allot funds for this work under Title VI of the Social Security Act. At the beginning of the war more than 30 states and several cities had established industrial hygiene services within their health departments. Only the armed services had made no provision for industrial hygiene except in a very limited way.

When the President declared a state of emergency in 1940, the various governmental agencies became more active in this field. The Army and Navy established industrial hygiene sections in their respective divisions of preventive medicine, while the Public Health Service started to expand its task force as early as 1940. It was not until May, 1942, that the U. S. Maritime Commission began to interest itself in the industrial health field. By the time war was declared there were approximately 500 industrial hygiene personnel in the country, exclusive of physicians in the practice of industrial medicine.

At the very beginning of the national defense program, the U. S. Public Health Service, through the Division of Industrial Hygiene, National Institute of Health, was asked by the Subcommittee on Industrial Health and Medicine of the Office of Defense Health, and Welfare Services to assume leadership in coordinating a nationwide industrial hygiene program. In view of the fact that the Division of Industrial Hygiene had developed over the years, in cooperation with the various states, a nation-wide industrial health program, it offered its facilities, both in the field of research and direct services, to the War and Navy Departments. Before outlining how such a coordinated program has been developed through the present emergency it may be well to discuss briefly the responsibilities of the various agencies in the war program.

NAVY PROGRAM

The U. S. Navy Department, aside from the men of military status, has the responsibility for the conservation of health of nearly 750,000 Civil Service personnel employed in approximately 700 naval stations. In order to meet this responsibility, the Navy Department created a Section of Industrial Health in the Division of Preventive Medicine of the Bureau of Medicine and Surgery. This Section of Industrial Health, in collaboration with the Office of the Assistant Secretary of the Navy, attempts to control the industrial environment in Navy shore establishments by analyzing occupational disability reports and by making recommendations in regard to the detection and elimination of potentially hazardous working conditions; by preparing information on various hazardous materials and processes; and by coordinating the efforts of the industrial hygiene field personnel.

To achieve these objectives, the Navy has a staff of more than 50 medical officers and 40 industrial hygienists, many of whom are engineers. These men have received postgraduate instruction in industrial hygiene and are now on assignment at the various Navy shore establishments attempting to solve the problems of lost time due to illness and injury, to increase production and efficiency, and to promote morale among the employees.

In the Navy industrial hygiene program the Office of the Assistant Secretary of the Navy is responsible for accident prevention, while the Section on Industrial Health in the Bureau of Medicine and Surgery is responsible for the protection of the general health of Navy industrial personnel. Although these functions are administered separately, they are very closely correlated. For example, the medical officers undertake the study of health hazards associated with occu-

pational activities, the conduct of technical surveys to determine potential or existing exposures, and the laboratory analyses necessary to evaluate such exposures. These observations and recommendations are made available to the safety officer, who is responsible for the application of the necessary control measures.

The Navy Department safety engineer serves as adviser to the Director of the Division of Shore Establishments. This division develops the standards for safety protective equipment used by the Navy stations and is responsible for the development of general safety rules for shore establishments of the Navy. The various Navy Department safety engineers make frequent field surveys of naval shore establishments and serve in a technical advisory capacity in problems of safety engineering. At each establishment a naval line officer is designated as safety officer and is responsible for the administration of the accident prevention program. He may be assisted by a junior line officer, and one or more civilian safety inspectors. At the present time the Navy has approximately 500 such safety personnel.

The Section of Industrial Health, on the other hand, serves in a liaison capacity to the other bureaus of the Navy Department, to the Maritime Commission, and to various nonofficial agencies. The Section also serves the seagoing Navy by aiding in the establishment of proper control of its industrial hygiene problems.

MARITIME COMMISSION PROGRAM

At the present time the U. S. Maritime commission is responsible for a working population of approximately 1,200,000 persons employed in Maritime and Navy contract yards. This does not include government-operated Navy yards. In general, the health and safety programs in these yards follow

very closely the recommendations laid down jointly by the U. S. Maritime Commission and the U. S. Navy Department in the minimum standards developed by these agencies.

The Maritime Commission has an industrial hygiene force loaned to it by the Navy Department, consisting of 3 medical officers functioning in the Atlantic Seaboard, Gulf Coast, and Pacific Seaboard regions, and 8 non-medical industrial hygiene officers, of whom some are engineers. The Great Lakes region has 1 engineer officer, but no physician. There is also a safety officer in each of these four Maritime Commission regions. All this work is coordinated under a Chief Health Consultant, cooperating closely with a Chief Safety Officer.

It may be seen from this brief description of the Maritime Commission program that the few personnel it has on industrial hygiene are primarily employed in a consulting capacity. Any technical studies which are needed in these yards, are, as a rule, performed by the various state and local industrial hygiene units in which the yards are located. More information on this phase of the work will be presented in the appropriate section of this report.

WAR DEPARTMENT PROGRAM

The Surgeon General of the Army was given the responsibility of overseeing the health of workers in all government-owned plants but the actual inspection of them was divided between that official and the U. S. Public Health Service. Those plants owned and operated by the government receive inspection by Army personnel. There are approximately 550 such plants employing roughly 800,000 civilians, all of whom are on civil service. These establishments include manufacturing plants—Ordnance, Chemical Warfare, Signal Corps, and Quartermaster Corps; fabricating and repair plants—

Ordnance, Air Force, and Chemical Warfare; explosives plants, bomb loading, shell loading, fuse and booster types—Ordnance and Chemical Warfare; while cargo shiploading plants come within the purview of the Ports of Embarkation.

In order to handle the problems in these plants operated by the government, the Surgeon General's Office has established an Occupational Hygiene Branch in its Division of Preventive Medicine, which has two medical officers and one engineer officer at its headquarters. The Occupational Hygiene Branch maintains a laboratory, whose personnel consist of 2 medical officers and 18 engineers. There are also in each Service Command and each Air Service Command an industrial medical officer and, in some, an engineer officer. The Army also attempts to maintain in all of its larger plants medical officers and in some cases engineers. There are, of course, in all of these plants contract surgeons and Civil Service physicians doing industrial hygiene work. All told, there are 120 medical officers, 60 contract surgeons, and about 20 Civil Service physicians for this type of work.

In the second category of War Department plants are those which are owned by the government but operated under contract. Although these too are a responsibility of the Surgeon General's Office, the Division of Industrial Hygiene, National Institute of Health, acts as the agent for the Surgeon General's Office of the Army in the inspection of these plants. There are several hundred of these plants employing approximately 750,000 workers. They are our largest producers of the tools of warfare. The Public Health Service constantly maintains in the field three inspection crews, each consisting of 1 general physician, 1 physician-dermatologist, 1 engineer, and 1 chemist. In addition, the necessary

supporting laboratory personnel for these crews are maintained at the Division's laboratories at the National Institute of Health.

For the purpose of coordinating the inspection work of the Public Health Service with that of the Army, an industrial hygiene unit was established at the Chicago headquarters of the Safety and Security Branch, Office of the Chief of Ordnance. A medical officer from the Army and a medical officer and an engineer officer from the Public Health Service have been assigned to this unit which initiates plant surveys, as needed, by personnel of the Public Health Service and of the Army Industrial Hygiene Laboratory. The unit also maintains general supervision over these activities, reviews critically the reports resulting from these surveys, makes follow-up visits to ascertain the effectiveness of control methods, and gives consultation on the most practicable methods of putting recommendations into effect.

Among other functions of this coordinating unit may be listed the development and promulgation of standard codes of medical services and engineering control of health hazards; the dissemination of new information; the review of safety audits made by the safety inspectors of the Ordnance office. From time to time meetings of plant physicians and engineers working in government plants have been held with the medical and engineering personnel of the Office of the Surgeon General of the Army and the Public Health Service.

PUBLIC HEALTH SERVICE AND STATE PROGRAMS

The above review of the Army program serves to describe an important part of the field work of the Division of Industrial Hygiene. No attempt will be made in this report to discuss the research work which is one of the

major activities of the Division. The other wartime industrial hygiene work of the Public Health Service is intimately concerned with the activities of the various state and local industrial hygiene units. It is through these units, in cooperation with the Public Health Service, that services are provided for the third type of plant engaged in the production of war materials, namely, the privately owned, privately operated plants, of which there are a great number and variety.

In 1940, the majority of state and local industrial hygiene units had merely skeleton forces, even for peacetime needs. The staffs usually consisted of a physician, an engineer, a chemist, and occasionally a nursing consultant. Only a few large industrial states, such as New York, Michigan, Pennsylvania, and Connecticut, had larger staffs, and even these were too small to begin to meet the needs confronting them. Furthermore, the state units immediately felt the inroads made upon them by the recruiting program of the armed services. In fact, most of the industrial hygiene personnel mentioned previously in this report as being attached to the Army and Navy, came from the state units.

The Public Health Service began recruiting and training personnel early in 1941, and obtained many of its men from the general public health field. In a few instances it has given Reserve commissions to state and local personnel, by arrangement with the respective state health commissioners.

At the present time, the total force of the state and local units consists of 46 physicians, 141 engineers, 22 nurses, and 45 other professional personnel, such as chemists. Of these 254 professional personnel, approximately 60 are on loan from the Public Health Service.

Some idea of the inadequacy of the present industrial hygiene forces in the

states can be obtained from a brief summation of the new responsibilities given these states and their accomplishments. For example, the War Manpower Commission is calling upon the Public Health Service, and through the Service upon the states, for the inspection of many private war plants to determine whether conditions are such as to warrant the release of men from some plants to others, because of alleged poor working conditions. A striking example is the high "quit" rate in the aluminum refining industry, where workers claim that unhealthy conditions in pot rooms make it difficult to work safely and efficiently. It is up to the Public Health Service and the states in which aluminum refineries are located to study these working conditions and render reports for the guidance of the local offices of the War Manpower Commission.

Again, the War Production Board has established more than 2,500 labor-management War Production Drive committees and has urged all of these committees to become active in the field of health and safety. These committees are calling more and more upon the Public Health Service and the state industrial hygiene units for advice and services.

The Provost Marshal General's Office, which has responsibility for internal security in all war plants, has recently arranged with the Public Health Service for the routine inspection by the state and local units of many private facilities coming under the jurisdiction of the Provost Marshal General's Office. Similar arrangements have been made with the Chief of the Office of Ordnance for the inspection of private facilities, and lately with the U. S. Maritime Commission for the inspection in the interest of health of several hundred shipyards located in 28 of our states.

No attempt will be made to cite the

various accomplishments of the federal forces, except to indicate that not only have all of the plants now in operation received initial inspections, but some have been surveyed several times. It is also gratifying to note in passing that as a general rule recommendations made by the various inspecting crews are put into force quickly. In so far as the state units are concerned, some idea of the extent of the ground covered may be obtained from a recent summary made by the U. S. Public Health Service for the fiscal year 1942. Approximately 6,000 establishments employing nearly 3,000,000 workers were covered by the state and local units in that year.

It is evident that although a nationwide coördinated industrial hygiene program exists, and although it is performing a difficult task heroically, still the amount of services rendered is far from adequate if we are to aid in maintaining work schedules and production by reducing lost time due to disability. It is therefore of paramount importance that everything possible be done to retain present personnel at their posts in the states. The Advisory Committee for the Procurement and Assignment of Sanitary Engineers of the War Manpower Commission recently revised its criteria for essential sanitary engineers in order to give more adequate consideration to those engaged in industrial hygiene work. The new definition of essentiality for industrial hygiene engineers takes into consideration the working population in each state, thereby insuring in nearly every instance that present forces will not be depleted.

FUTURE CONSIDERATIONS

This report has attempted to present the highlights of the industrial hygiene program of official agencies in the present war effort, and the responsibilities involved in the maintenance of

the health of our war workers. The manner in which the industrial hygiene program has been organized, developed, and carried on has also been briefly depicted. Those developing this nationwide program attempted to accomplish a dual purpose: (1) to meet quickly and effectively the demands on industrial hygiene services created by the war production program, and (2) to create an organization which would function in the peace years as well as in the war emergency. The program was developed on a sound and permanent foundation with the realization that the need for industrial hygiene after the war will be even greater than it is today. Many of our problems may be similar in character, but they will certainly be wider in scope.

To mention but a few of the problems in industrial hygiene which will confront this nation, one should list such items as the problems created by the return of service men to their former jobs; programs for men let out of war industries, for the reconversion of these industries to peacetime production; plans for rebuilding cities and terminals; new transportation facilities; research; and services in the fields of health, nutrition, medical care, education, and recreation. There will be the important problems of rehabilitation, both physical and vocational, of our fighting army, as well as our army on the production front. Plans are even now being considered for broadening the scope of social insurance, for labor and its participation in the new expanding economy, including not only working conditions, rates and hours, but also relations with management and the consumer, and the training of new skills.

These and many other problems which will confront us in the peace years should be the concern of industrial hygienists. In order to meet them effectively, however, we should begin

now to train additional personnel and to provide additional funds for these programs. We shall certainly be better prepared to meet these post-war problems in industrial health than ever before. By the end of this war, through the efforts of all the agencies now engaged in industrial hygiene work, more professional people will find themselves versed in industrial hygiene skills. Management, labor, and the public will have come to accept industrial hygiene as commonly as they now accept other health services. Legislation will need to be extended and made more uniform in order to protect the working population against industrial health hazards, while emphasis on industrial health services in the small plants will need to be considered and extended.

Only a few of the problems and opportunities which will confront the industrial hygienist after the war have

been mentioned. To make sure that these future activities receive proper guidance and implementation, those who have the knowledge and the responsibility in the field of public health must accept the challenge and begin now to take part in the planning. Engineers have a major rôle in this planning. They have never been lacking in vigor, vision, and the knowledge to take the initiative; and both labor and management will welcome our taking our rightful place. This will all be possible because, as already indicated, the present wartime industrial hygiene program has been built not as a temporary expedient but on a firm and solid foundation.

Wartime Shellfish Problems*

Engineering Section

ON account of the war, only those members of the committee who were able to attend the annual meeting of the National Shellfisheries Association, met at Philadelphia in June, 1943. A few other persons interested in the technical and scientific problems of shellfish sanitation attended.

It was the consensus of opinion of the committee members that because of the man power shortage and scarcity of materials needed to keep plant and equipment at par, normal sanitary standards would be more difficult of attainment during the coming season than is normally the case, and would become more difficult the longer the war continued. For this reason, it was agreed that the vigilance of all those responsible for the cleanliness and safety of shellfish needed to be redoubled. Although additional vigilance is called for, unnecessary refinements, yielding little or no additional protection to shellfish consumers, should not be suggested in wartime when normal supplies of materials and labor are lacking. It was agreed that a progress report recounting the present status of shellfish sanitation and inviting attention to the problems still confronting the shellfish regulatory officials and the industry would be desirable. This report is therefore presented.

Since in many shellfish producing states, it is the responsibility of sanitary engineers to decide which areas

shall be closed, and since wide divergencies appeared in conclusions reached as a result of sanitary survey and as a result of laboratory examination, this committee, in its 1936 report, invited attention to the need for a more satisfactory bacteriological check on the safety of shellfish offered for human consumption and also for a reëxamination of the bacteriological methods employed in checking the safety of shellfish growing areas from which shellfish might be marketed without further processing. Such studies were begun by the Public Health Service but were interrupted by the war.

A committee from the Laboratory Section of the Association at its 1942 meeting recommended, and the Association has recently adopted¹ a suggested method for the examination of shellfish. Important modifications of the methods recommended by the Association in 1912 have thus been made. It will be interesting to many, and important to the shellfish industry, to see whether closer correlation between results found on laboratory examinations, as obtained by following the new standard methods, and the results obtained by sanitary survey can be attained. It will also be interesting and important to see whether oysters, soft clams, hard clams, and mussels will show equal degrees of contamination when taken from the same growing areas, and whether real significance can be attached to results obtained from the bacteriological examination of shellfish

* Progress report of the Committee on Shellfish.

COMMITTEE ON SHELLFISH (Engineering Section)

Organized 1928. Published reports: *Year Books* 1934-1935, 1935-1936, 1936-1937, 1937-1938, 1938-1939, 1939-1940, 1940-1941.

found on the markets of interior cities. These are some of the problems still confronting regulatory officials and the shellfish industry.

In addition to these, there are special problems of sanitation brought on by wartime conditions, some of which are discussed briefly below.

SOME OF THE WARTIME PROBLEMS

1. Changes in boundaries of closed shellfish areas have become necessary in certain areas because of increasing quantities of sewage partially treated or untreated, discharged into nearby shellfish growing areas due to the concentration of war workers in coastal areas, near shipyards, or at marine, military, or naval bases.

2. Finding suitable container material for shucked shellfish to take the place of tin has become a problem for packers of shucked shellfish and regulatory officials.

3. Evaluating the effectiveness of shellfish sanitation measures more carefully and more scientifically than heretofore has become of prime war time importance because of man power shortages.

4. Methods to encourage greater production and consumption of shellfish foods have brought new problems to areas where mussels are being harvested and to areas where intensive cultivation of oysters and clams are being employed.

The Army's inclusion of sea food as a portion of the diet of troops has tended to intensify these problems so that members of the shellfish industry have urged regulatory authorities to remove restrictions on contaminated areas to make it easier to meet increased demands.

1. Changes in boundaries of closed shellfish areas—The great expansion of military, naval, and industrial areas along the coast on salt water estuaries or tributaries has, in some instances,

made it necessary to close large areas of productive shellfish grounds because of increased quantities of sewage being discharged into waters tributary to such areas. The movement to reduce the pollution of large bodies of coastal waters was making good progress when the war broke out. The demands of the war for ferrous materials practically put a stop to the use of such materials in sewage treatment projects, except in those projects essential for the protection of public health. The result has been that sewage treatment projects needed for normal civilian population increases have been almost impossible to obtain.

In view of the increasing importance that attaches to the efficient production of food for ourselves and our Allies, it does not seem unreasonable to your committee to expect that reasonable quantities of critical materials should be released by WPB for sewage treatment works where increased quantities of sea food could thus be made available. Since shellfish are good substitutes for meat which is very much needed in the war effort, and since they are sources from which important food elements needed by the body can be obtained, it seems reasonable that their production should be fostered in times of food shortages such as now prevail. The oyster crop now is equivalent in food value to about 400,000 dressed steers yearly.

2. Experiments with various materials seem to indicate that containers made of black steel, coated with a suitable coating, are the best substitute thus far found for packing shucked shellfish. It appears to be better suited for containers of shucked shellfish than either glass or heavily paraffined fiber, since it is a close imitation of the tin cans so extensively used heretofore in the industry, and can be used with machinery now installed in packing plants.

3. Evaluating the effectiveness of necessary shellfish sanitation measures in such a way as to disclose accurately the degree of compliance with sanitary requirements improves the efficiency of control measures. In times of man power shortages, maximum efficiency is essential.

A short time prior to his death, Leslie C. Frank suggested that the same principles used in developing milk sanitation programs could be used effectively in shellfish sanitation practices. These principles are, briefly:

1. The sanitary requirements must be accurately stated.

2. The public health reason to justify the requirement must be given.

3. A clear statement of what constitutes satisfactory compliance must be enunciated.

4. If the relative importance of each requirement can be indicated by assigning a weight which is commensurate with the importance of the requirement, then the percentage of compliance attained can be approximately expressed with a single figure, e.g., 60 per cent, 80 per cent, 90 per cent, etc.

The preparation of a manual of shellfish sanitation requirements, based on the above principles, was begun before the war. Some of the members of the committee have participated in its preparation. It seems probable that the manual may be put to an unofficial trial during the present shellfish season, and constructive criticism can thus be invited before it is officially adopted as a guide for determining compliance with requirements. It is believed that the use of this manual will add to the efficiency and effectiveness of the work of shellfish inspectors, will tend to bring about uniformity of enforcement throughout the entire shellfish industry, and will gradually bring about a correction of insanitary conditions. Those interested in obtaining a copy of this shellfish manual should write to the Surgeon General, U. S. Public Health Service.

4. Methods for increasing the production of shellfish foods—These methods fall under four principal heads: (a) the wider utilization of mussels; (b) the exploitation of deep sea shellfish areas, such as deep sea clam areas; (c) the more intensive cultivation of inshore shellfish areas both for oysters and for clams (An intensive method of oyster culture recently demonstrated in America is described in this report.); (d) the purification of shellfish from moderately contaminated areas and the transplanting of shellfish from such areas into clean waters.

The wider utilization of mussels on the Atlantic and Pacific coasts calls for increased vigilance in avoiding cases of mussel poisoning. Two wholly different types of mussel poisoning occur. One apparently occurs only in the California mussel (*Mytilus californianus*). A wholly different form of poisoning may occur from eating the Black Sea mussel (*Mytilus edulis*) now being widely advertised. It is claimed that it is dangerous to eat black mussels which are so far gone that their shells gape. Fisheries and market inspectors should be warned to be on the lookout for gaping mussels and to warn the trade to be careful not to include such mussels in shipments or in the retail trade. Mussels are sensitive to high temperatures; hence it is even more important to store and ship them at low temperatures than is the case with clams or oysters.

Cases of mussel poisoning occurring on the Pacific coast have attracted the attention of scientists for many years. Methods for determining the presence of the chemical poison responsible for causing the illness have now been developed.² Sufficient study has been directed to the problem of mussel poisoning to indicate that the trouble is seasonable and is apparently due to the reaction produced by the presence in the diet of a high percentage of

the dinoflagellate *Gonyaulax catenella*. This indicates a method for dealing with the problem.

The utilization of deep sea clams and other shellfish calls for a special method of food preservation and marketing, and does not seem to present any particularly difficult sanitation problems.

The more intensive utilization of inshore shellfish growing areas calls for increased vigilance to avoid accidental sewage contamination of the shellfish. The committee has, in the past³ made recommendations for dealing with hazards incident to the floating or water storage of shellfish, and its recommendations have been incorporated in the U. S. Public Health Service Minimum Requirements for endorsement of state shellfish control measures and certifications for shippers in interstate commerce. As the intensive utilization of inshore areas increases, the importance of the committee's recommendations for dealing with these hazards increases, since these areas are close to the sources of pollution and are not protected by dilution, because they are located in shallow water.

In recent years, the intensive cultivation of oysters for the half shell trade, by placing them on trays supported a little above the bottom in areas where they are exposed at low tide, has come into commercial use in this country. Modifications of this method have been practised since the early days of the Roman Empire, and by the Chinese for hundreds of years.

The very rapid growth of the oysters, and the extra price obtained for them, may lead to the more extensive utilization of this method of oyster culture in this country as it has in Europe, notably in Belgium and France.

A detailed description of the practice, as employed currently in portions of Virginia, is included here.

INTENSIVE OYSTER CULTURE

Our reason for describing this method of oyster culture in this report is because we are led to believe it can greatly increase our sea food resources at a time when increased food production is important, and to point out certain sanitary precautions which should be observed whenever this method of oyster culture is employed.

The method consists in placing approximately 2 year old oysters, from northern waters, in baskets or trays supported from 6" to 30" above the bottom in suitable southern shellfish areas. The oysters are bare or uncovered at low tide, and covered at high tide. In about 6 months, they attain a size equivalent to that of 5 year old northern oysters.

A well established concern in Virginia has been employing this method successfully for 5 years, with remarkable results. Members of your committee have seen the astonishingly rapid growth attained. Dr. Thurlow Nelson, of the New Jersey Experiment Station and of Rutgers University, showed in experiments on the Delaware shores of Cape May, the phenomenal growth and excellent shape that could be obtained. These demonstrations were made about 1920.⁴

Among the factors responsible for the growth are the following:

1. The oysters are in the upper layers of the water, where the temperature is relatively high and the effect of the sunlight produces a plentiful supply of microscopic food, probably of superior vitamin content because of irradiation by sunshine.

2. The shellfish are above the mud and sand where particles of inert material do not become mixed with the food and cause rejection and waste of food. The oyster rejects what is not considered food on the basis of *size of particles*. Consequently, when over-size sand grains or mud particles get

into its food, the mixture is rejected and the slow process of straining food particles out of the sea water must be started all over again. This rejection hardly ever becomes necessary when the oyster is supported above the bottom. Consequently, the amount of food which the oyster ingests is greatly increased and growth is correspondingly more rapid.

3. Northern oysters, when transferred into southern waters, grow very rapidly. Stimulated by the warm water and the abundant food supply, they function vigorously during the 18 hours they are under water, pumping in and expelling from 40 to 80 gallons per oyster per day.

4. During the period when the shellfish are out of water, they learn to adjust themselves to their new environment. The adductor muscle, which holds the shells in a closed position, is strengthened so that oysters grown in this way stand shipment better than oysters which have not been out of water before. The French refer to this as "educating" or "conditioning" the oyster.

5. The oysters are protected from their natural enemies such as starfish, drumfish, and mud worms. If attacked by drills, they can be readily discovered and removed at low tide.

A suitable area must be selected, protected from storms, in shallow water where stringers supported on stakes or piling can be erected so that they, in turn, can support the trays or baskets. There must be freedom from navigation hazards, proper and abundant food for the oysters, and adequate safeguards from the sanitary standpoint.

The importance of sanitation becomes readily apparent. Suitable areas are usually found near land where most contamination originates. They are found near the mouths of creeks, which bring in much of the food and may bring in contamination also; and they

are found in shallow water which warms up readily, but which does not afford much dilution of such contamination as may find its way into the area accidentally. The precautions that need to be observed are similar to those recommended for the protection of shellfish growing areas from which shellfish may be marketed directly or for areas used for the water storage of shellfish, except that vigilance should be increased.

Fecal discharges from employees working in the areas should be buried or otherwise disposed of on shore, in a location and in a manner approved by the state health authorities: Approval of the method of disposal should not be left to local sanitarians or to part-time health officers. A special permit, showing precisely the boundaries within which intensive inshore oyster culture may be practised, should be obtained in each instance from the state health department. Without such permit, it should not be allowed.

The low salinity portions of the area can be used for seed production and the higher salinity areas for growing and maturing grounds. This has been the practice in Delaware Bay for many years.

Details of this method as practised in Virginia are as follows⁵:

Welded steel trays that will deliver a bushel of oysters when they have grown to medium size are used. They are 16 x 40 inches in plan, and 3 inches deep. They are dipped into high temperature tar, such as is used to coat the inside of water pipes. That a serious fire which may destroy the coated trays can occur unless care is used, has been demonstrated by experience.

The trays are supported on heavily creosoted wooden stringers, in such manner that there is at least a 6" space between the under side of the tray and the mud bottom below it.

The trays are set out in rows 30 feet center to center. At low tide, small scows are poled between the rows so that work on the trays and the oysters in them can be done from the decks of the scows. Much labor is required. Each of about 250 oysters is placed on the tray by hand, hinge down. They are held upright by a wooden brace placed in one end of the basket. As the oysters expand because of growth, the tray must be repacked in order to maintain the vertical position of the oysters.

The initial capital investment need not be large. It can be profitable only, however, through the production of high grade stock for the half shell trade which will command good prices. The process is not, in its present state of development, suitable for the production of oysters to be sold to shucking houses at presently prevailing prices. The process may have tremendous potentialities for increased food production if so developed that public confidence in the safety of the product is not impaired. It offers a challenge to members of this Section to develop mechanical labor saving devices which will reduce unit pro-

duction costs and produce a product of unquestioned purity in great volume. If some member of this Section succeeds in contributing a productive idea to this problem, this report will be considered to have been worth while.

Nutrition as a Science in Wartime*

Food and Nutrition Section

THE major function of our committee through the years has been to focus attention upon specific areas of research that merit special attention. The present report deals with three topics: (a) the need for certain types of fundamental research through the war period; (b) research that is specifically geared to winning the war; and (c) the need for research that will give a clearer picture of the contribution that nutrition can make to public health.

FUNDAMENTAL RESEARCH DURING THE WAR

In time of war every research program should be critically examined with respect to its demands upon personnel and materials. But such an examination should be conducted with discipline and considered judgment rather than leaving the course of action wholly subject to a natural impulse to drop everything and be off to war.

The following quotation provides a good statement of principle, from President Raymond B. Fosdick's *Annual Report of the Rockefeller Foundation* (1941, p. 7):

This concern for the future is a matter of stern, practical sense. The specialized talents and abilities that are meeting this emergency and those that will meet emergencies to come are not produced by feverish last-minute activities. No amount of pressure can suddenly create a supply of thoroughly trained and broadly experienced physicists, mathematicians, chemists, biologists, economists and

political scientists. These men represent the trained intelligence without which a war cannot be won, or a lasting peace achieved. They emerge . . . out of long, patient, and sustained effort. Pure research, the clean urge to gain new knowledge, the sympathetic appreciation of imaginative scholarship even when it seems remote and unrelated—these we must steadfastly sponsor or our vital intellectual resources will fail us in the days to come.

The science of nutrition is so closely interwoven with other basic sciences and with immediate health problems of the armed forces and civilian groups, that cessation of research, in specific cases, may be too costly in terms of results to justify the transfer of personnel and facilities to immediate war problems. Aid in solving difficult problems relative to personnel deferment has been given in appropriate cases by the Food and Nutrition Board of the National Research Council, through a Committee on Research Personnel, under the Chairmanship of Dr. C. A. Elvehjem.

The following examples may serve to illustrate types of research in nutrition that have been recognized as justified in wartime:

1. Factors that bear closely on blood formation, bone healing, recovery from burns and trauma, shock, and resistance to neuroses

2. Studies of nutrition in relation to chemotherapy, especially with reference to the use of sulfa drugs, arsenicals, and anti-malarials

* Report of the Committee on Nutritional Problems.

COMMITTEE ON NUTRITIONAL PROBLEMS

Organized 1919. Published reports: *A.J.P.H.*, Jan., 1920, Feb., 1921, Feb., 1922, Dec., 1924, Feb., 1926, Dec., 1926, Mar., 1928, May, 1929, Nov., 1929, *Year Books* 1930-1931, 1931-1932, 1932-1933, 1933-1934, 1934-1935, 1935-1936, 1936-1937, 1937-1938, 1938-1939, 1941-1942.

3. Isolation and assay of the less stable nutrients in foods, for example the newer vitamins known to be required by guinea pigs and monkeys, but concerning which little is known with respect to human needs

4. Studies of the minimal and optimal human requirement for amino acids, vitamins and other nutrients that are likely to be deficient in military and civilian wartime diets

5. Relations between nutrition and environment, so that physiological principles can be followed with greater assurance beyond the confines of an air-conditioned room, out into the desert, the arctic, and to high elevations

6. Improvement in certain types of bioassays so that food production, processing, storage, and utilization can be measured with greater accuracy and economy

7. Studies of the nutritive value of foods, in cases where such information is critically important to the national and world need

There should be sober recognition of the fact that no one can predict how long the war will last. Planning for munitions and other war supplies cannot be limited to provisions based upon an assumption that the war will end in 1944. Neither can we limit food production and human nutrition plans to accord with such a simple assumption, however attractive. Leaders in research should be first to recognize that as the length of the war increases, the prospect is heightened that relatively fundamental studies will make important contributions toward winning the war. And in addition we must give some consideration to the contributions that will aid humanity in recovering from the war and in setting their faces toward a brighter future. The hazard is very real that within many organizations research planning during the war will be too short sighted with respect to the assignment and training of man power. Even in planning direct war research there is a similar risk of being wastefully hurried in perspective.

A more specific definition of the areas of research cited above may be helpful.

1. *Recovery from trauma*—The provision of "blood banks" is everywhere acclaimed as a major factor in saving the lives and speeding the recovery of soldiers, sailors, and civilians caught in the immediate physical wreckage of war. Less dramatic but significant contributions to the problem of providing for blood regeneration have also been made during the year, giving a better understanding of procedures that can be used to protect military personnel and civilians. Again, the relation of nutrition to the healing of wounds and bone fractures has been clarified by recent work, and there are strong indications that shock and the tendency toward neuroses may be more severe when there is marginal malnutrition.

2. *Chemotherapy and toxicology*—Numerous publications have pointed toward the need for greater consideration of nutritional status during periods of intensive chemotherapy and exposure to toxic chemicals in war plants. Of special interest are the war-essential nitro compounds and industrial hydrocarbon vapors; yet the evidence that has been presented is so fragmentary that nutrition has been given only minor consideration in many manufacturing plants using or producing such products.

There have been numerous indications, too, that tolerance to intense chemotherapy is conditioned in part by marginal degrees of nutritive deficiencies. There are also scattered indications that intense chemotherapy may cause an accelerated depletion of certain nutrients from the body. In view of the current scale of administering sulfa drugs, antimalarials, and arsenicals, it is evident that the need for additional information regarding nutritional aspects of the problem is relatively great.

3. *New vitamins*—The feeding of troops and civilians on restricted types

of rations that must be processed and packaged long in advance, followed by storage in hot climates, involves practical nutritional problems of major magnitude. The losses in ascorbic acid, thiamin, and other known nutrients can at least be measured, and they are known to be severe; hence they can be compensated for in some degree by supplying synthetic vitamins. But there is good reason to remember that the vitamin requirements of man have not been critically studied. At least one of the newer factors required by guinea pigs is relatively unstable, but practically nothing is known of its content or loss in special rations, nor do we know whether it is required by man. Information of this nature may be very important if the war lasts through another year or two.

4. *Human amino acid requirement*—There has been world-wide concern over the increasing stringency in supplies of high quality proteins, both for direct human consumption and for animal feeds. In addition to the problem of limited supplies, the problem of cost will assume increasing importance. Even in peacetime there is a constant problem of meeting the need for high quality proteins within the price ranges that can be reached by low income groups. Basically the problem of protein requirement is one of supplying adequate quantities of the individual amino acids; yet the evidence concerning amino acid requirements of man and farm animals has been extremely limited. The finest progress made on this fundamental problem has been carried out since the beginning of the war.

5. *Nutrition and environment*—The whole field of human requirements for specific nutrients, in a quantitative sense, has been very inadequately explored. Most of the fragmentary information available at the beginning of the war was based upon environmental conditions typical of comfortable labo-

ratories, and with subjects that were physically and emotionally "relaxed." Conditions typical of military life in the tropics, ski trooper service, high altitude flying, and submarine life, together with extreme ranges in energy output, fatigue, and nervous tension had scarcely been studied in relation to modern concepts in nutrition.

Since the beginning of the war, several laboratories have undertaken intensive studies in each of the above fields, but most of the reports from such projects have been classified as "restricted" by government agencies, so that a recapitulation of the data cannot be made. It should be pointed out, however, that there are still many gaps in the information available to government agencies, and that qualified research organizations having an opportunity to undertake work in this general area could probably receive a certain degree of guidance from the National Research Council.

6. *Bioassays*—Improvements in specificity, accuracy, or time requirement of bioassays contribute so much that there is constant need for intensive effort in that direction. As each factor is identified, the possibility of developing chemical and physical methods of assay is greatly enhanced.

7. *Nutritive value of foods*—Civilian food supplies are likely to become more and more restricted as the war continues and many of the difficulties are likely to persist into the post-war period. Hence our food resources should be developed with special concern for their protection of health, economy of production and distribution, supplemental relation to other foods available, and adaptation to war-time usage. Such a program cannot be developed effectively without regard to the initial nutritive value of our common foods and the retention of nutritive qualities until consumed. Processing, storage, and final preparation

losses should be assessed with care to avoid too great optimism concerning the nutritive value of a given food supply.

Estimations of nutritive intake according to tables that are based upon "edible portion as purchased," involve gross errors. Losses of 30 to 90 per cent of some of the vitamins and minerals from vegetables and fruits during the interval between purchasing and serving are common. It is grossly misleading, therefore, to neglect consideration of the probable or actual content of nutrients in foods "*as consumed*." On the whole, large scale food processors have been more cognizant of this problem than merchants, housewives, restaurants, hospitals, and other food dispensing agencies. In other words, the need for exploratory types of research on food composition should be carefully balanced against the need for information about losses.

The program of supplying dehydrated foods for use at distant points in the tropics has encountered a series of major difficulties, many of which are nutritional in nature. The exposures to tropical temperatures are too severe for most conventional products to stand up. Losses in flavor, vitamin content, and attractiveness have been greater than expected. Some of the problems are being solved by better control of moisture content, better packaging practice, high sulfite content when processed, and simply eliminating many conventional types of products.

Among the food products that offer great promise for more extensive use in America, special attention should be given to soybeans, because of their high nutritive value and the low cost of production. The horizon for this food item is very bright, but we should not underestimate the seriousness of the snags between production and acceptance.

AVIATION

No other area of war activity seems to be more critical than aviation with respect to victory. The highly specialized field of aviation medicine had only a brief opportunity for development, in the sense of war needs. Two major stresses are frequently imposed on the body during flying: (a) a decreased supply of oxygen and (b) a lowered atmospheric pressure. Added to these stresses frequently are extremes of temperature, intense light glare, night flying, intense acceleration, deceleration and centrifugal stress, prolonged nervous strain, confinement in position, and irregularity of schedule. Those who are familiar with the complexity of physiological adjustments that are demanded by the above stresses can readily realize that there is need for intensive research on the problems, from a nutritional point of view. Chronic fatigue, gas distention, mild and acute anoxia, alkalosis due to hyperventilation, changes in steroid metabolism, impaired vision, diuresis, and changes in excretion of respiratory catalysts are among the recognized disturbances caused by altitude exposure. Obviously there is a reasonable prospect that nutrition would have a bearing on the body's performance under the influence of such stresses, and there is an obligation upon research laboratories to help find answers to the many questions that are involved, whether they work from wartime or peacetime motives. The latter point is mentioned because it is felt that clear provision should be made for the coöperation of the Selective Service Office in making arrangements for men classified as conscientious objectors, to serve as experimental subjects on government sponsored research projects. The contribution of such studies to protection of civilians and the advancement of aviation medicine is very real.

Influence on temperature—There have

been relatively few studies to indicate the optimum proportions of protein, carbohydrate, and fat for the best maintenance of physical vigor in such areas as the tropics and the arctic. Nearly all of the data available with respect to diet and working efficiency have been obtained under moderate conditions of environmental exposure. There is a good theoretical basis for expecting differences in performance in response to variations of the above type.

A number of papers have given preliminary indications of higher requirements for the water soluble vitamins when men are exposed to high temperatures. The evidence available is extremely fragmentary, however, and not in agreement as reported from different laboratories.

Long before the war it had been generally accepted that exposures to high temperatures made necessary a higher intake of salt to balance excessive losses in perspiration. Observations in mines and mills had led to routine provision of extra salt for workmen. A number of the related problems had not been adequately solved, however, in a manner that would meet the requirements of either the civilian or military personnel operating in tropical areas. Even the quantitative correlation between salt requirement and perspiration had not been established satisfactorily as a basis for maintaining optimal work output, nor was there clear evidence with respect to the best manner of administering the added supplies of salt. Some physicians advocated salt pellets, others advocated salt in the drinking water, and still others preferred to supply salt with the regular food intake. Tests carried out since the war began make it clear that there is a difference in the performance of men, depending upon the method of administering salt.

Thirst—Desert operations and provision for stranded groups, such as may

occur on life rafts, often make it necessary to utilize with utmost efficiency limited and inadequate supplies of water and food. One will not find in the literature adequate evidence to indicate the most efficient manner of utilizing limited supplies for maintaining survival.

Partial inanition—Neither is there adequate information with respect to the optimal composition of foods that should constitute emergency rations where there is a prospect of prolonged caloric insufficiency. The proportions of carbohydrate, fat, and protein, and the content of minerals and vitamins would almost certainly have a bearing upon survival through prolonged periods of diminishing food supplies.

Shock—The possible influence of special dietary regimes to afford optimal conditions for recovery from shock, or resistance to the stresses that induce shock, such as trauma, severe hemorrhage, explosions, and exhaustion, has not been explored to the degree that the importance of the subject seems to justify.

THE PUBLIC HEALTH ASPECTS OF NUTRITION

Among research workers who have studied most carefully some of the relationships between nutrition and health in experimental animals under rigidly controlled conditions, there is considerable confidence that improved human nutrition, well above the levels that protect against deficiency diseases, would contribute in a very significant way to better public health. Many physicians and students of public health are in agreement with that point of view. Nevertheless it must be granted that the amount of evidence obtained under satisfactorily controlled conditions is relatively inadequate, and that as a result many professional people in such fields as medicine, public health, education, industrial management, and civic

administrations are not fully convinced of the importance of nutrition.

Among the more significant clinical studies in recent years may be cited the study by Burke, Beal, Kirkwood, and Stewart; earlier studies by Ebbs, Scott, Tisdall, Moile, and Bell of Toronto; and the reports by Sir John Orr and his associates in England. If the relationship between diet and health that is indicated by the above three studies holds for a large proportion of our population, then the entire subject of nutrition, both from a research and from an applied point of view, would seem to merit a much larger degree of attention than it has received.

Among the public health areas of study that would seem to afford great promise for nutrition research, the following may be cited:

1. Maternal nutrition in relation to the health of mothers and infants
2. Infant nutrition in relation to both physical and mental development
3. School and community feeding programs that will provide for better nutrition during childhood and adolescence
4. Adult nutrition as a means of maintaining a more satisfactory level of health, particularly with respect to protection against metabolic and neurological disturbances that commonly accompany approaching old age. The latter field of research has scarcely been touched, even though there has been a considerable expression of interest in the "science of geriatrics," and a few groups have been organized to give the subject more intensive consideration.

There is general agreement that the current incidence of dental caries in America and in nearly all other sections of the civilized world constitutes a health impairment of very great importance. There are many different

theories with respect to the major factors involved, but there is little clear-cut evidence that is generally acceptable to critical students of the problem. With a record of approximately one man in five rejected because of dental defects, of those rejected on physical examination for the United States Army during the early period of the war, concrete evidence was provided concerning the importance of the problem. Many other studies have been reported in the literature to supplement the observations with respect to men called for military service.

Three great difficulties have stood in the way of progress in studying human nutrition: (1) the lack of adequate controls during the course of observation; (2) the shortness of time during which careful observations have been made (e.g., in contrast, Professor Sherman's rat experiments now correspond roughly with human time reaching back to the reign of the Caesars); and (3) the relatively high cost of conducting well controlled experiments. With adequate interest and planning, however, it should be possible to overcome enough of the handicaps to secure the information that is most critically needed.

Food Conservation*

Food and Nutrition Section

THIS country has never faced a more critical period in respect to its food supplies than the months and years immediately before us. Despite an abundance of many United States food crops during the past two harvest seasons, with the highest levels ever reached, our obligations to feed our armed forces, our civilian population, and materially aid our Allies and the population of such other areas as may be necessary, will cause an unprecedented demand on every type of available food supply.

A part of this demand may be met by additional emphasis on food production. With the limitations of man power, agricultural equipment and supplies which exist due to the war effort, this approach to the problem, worthy as it is, cannot be expected to provide a complete solution.

We must also embark on a planned program of food conservation, worldwide in scope, geared to recent and accurate scientific information concerning food utilization in the most efficient and least wasteful methods. Such a program must start on the farm where crops are planned and planted for specific purposes, and end not at the table as in the past but at the chemical plant where wastes of the table are reconverted to foods, feed, or fertilizer for further use in growing more foods.

Such a program will be intimately concerned with the health and morale of our population, the economic status of our citizens, and the success and timeliness of our war effort, because foods are no longer only foods. Foods are also to a considerable extent the raw materials of our munitions industries, our textile industries, our plastics industries, and others. Our pharmaceutical industries depend on foods for the raw material source used as the basis for the production of the new and vitally important drug, penicillin, which has shown such remarkable life-saving properties.

Recent developments in the field of nutrition indicate that much could be done to improve the diet of a large percentage of our population without making changes which are either restrictive or unpleasant. With the strides which have recently taken place in respect to vitamins and proteins, we are much better equipped to supplement the gaps in nutritional inadequacies by the use of simple foods and by-products of peanuts, soybeans, and the dairy industry. The residues of cereal germs after removal of their valuable oils have attained recognition as valuable potential foods for man as well as feeds for meat-producing farm animals.

The hydrolysis of protein residues gives promise of additional amino-

* Report of the Committee on Foods (Except Milk).

COMMITTEE ON FOOD (EXCEPT MILK)

Organized 1932. Published reports: *Year Books* 1933-1934, 1934-1935, 1935-1936, 1936-1937, 1937-1938, 1939-1940, 1940-1941.

acid containing foods of high biological value.

Adequate conservation of our food supplies will require the leadership of our most inspiring and able workers in every profession, including medicine and public health. It will require the understanding and coöperation of every man, woman, and child in this country and in others. To accomplish the goal will require the greatest mass effort in health education that has ever been projected. It can pay dividends in the improved welfare of our people and, simultaneously, contribute in a large way to the war effort.

Some of the factors concerned in the effective formulation of such a program are the following:

1. Conversion of agriculture to crops which produce
 - a. More food per unit of area
 - b. More nutritious foods per unit of area
 - c. More food per unit of man power expended in production
2. The consumption of smaller total quantities of food without losing nutritional value by
 - a. Better choice of foods in the diet
 - b. Elimination of inefficient foodstuffs
 - c. Insuring that those who get too much food use less, and those who are on a poor diet get more of the needed commodities
 - d. Wider utilization of food by-products of high nutritional value
3. The prevention of food losses, caused by
 - a. Improper storage—absence of refrigeration
 - b. Poor and possibly unsafe processing methods
 - c. Poor packaging methods causing wastage
 - d. Improper and excessive cooking which lowers vitamin content
 - e. Faulty use of prepared foods, such as discarding cooking water
 - f. Preparation of excessive quantities of food for the number of persons to be fed
 - g. Ignorance of means by which food residues may be used in other forms
- h. Plate waste—the serving of more food than an individual can utilize at the time
- i. Waste of fats which may be salvaged either in the kitchen or by installing grease traps in larger institutional cooking establishments
- j. The possible extension of garbage disposal facilities in municipalities with fat recovery—or garbage feeding of swine
- k. Failure to consider the enormous food savings involved in meat cutting and trimming in centralized agencies where all excess fat and bones may be rendered for subsequent food uses
- l. Failure to consider the food wastage involved in feeding domestic pets which are consuming food that could feed thousands of humans

No doubt there are other considerations involved which are equally important. If each of these mentioned were thoroughly studied, however, and if every member of this Section and this Association were to expend his own utmost endeavors to correct such defects and help to activate a moving program along such lines, it would result in a great boon toward victory, toward better health for more people, and to a better world in the future.

A start in this direction could be made by the collection and publication of data on food losses by the members of the Food and Nutrition and the Laboratory Sections. The Health Education Section could coöperate in the preparation of proper media for the presentation of such information to the public. The Governing Council could collaborate with and aid those government agencies which are concerned in various phases of this type of food conservation.

It is the recommendation of this committee that a resolution be presented to the Governing Council of the Association indicating the desirability of a national food conservation campaign and the willingness of this Association to sponsor and contribute in every possible manner to the fulfillment of any program or duties

relating to the same which would facilitate the conservation of food in the war effort.

West Indian Conference of the Anglo-American Caribbean Commission

The West Indian Conference of the Anglo-American Caribbean Commission was held in Barbados, British West Indies, during the period March 21 to 30, 1944. The meeting was attended by a large group of delegates and technical advisers from British and United States territories in the West Indies, in addition to members and advisers of the British and United States Sections of the Commission. Observers were sent

by the Netherlands and the Canadian Governments.

Of the six general topics considered, three related to medicine and public health. These were: (1) Health protection and quarantine, (2) the planning of public works and thereby the provision of better facilities for environmental sanitation and medical care, and (3) the establishment of a section on public health and medicine of the Caribbean Research Council.

II. Vitamin B Complex

Status of Assay Methods and Need of These Substances by Man*

Food and Nutrition Section

THE three most widely used members of the vitamin B complex were discussed in detail in the last prepared Committee Report given at the Detroit meetings in October, 1940.¹ Since that time clinical and laboratory findings have further elucidated the deficiency diseases resulting from lack of thiamin (B₁), riboflavin (B₂), and nicotinic acid (niacin). In fact, the diseases resulting from a lack of one or more of the above were known before the individual vitamins were isolated and synthesized. However, once this was accomplished, great progress was made in the matter of assays either by microbiological or physico-chemical methods. This meant a great saving in time as the application of such technic obviated the necessity of long-time animal assay methods. Since more refined assay methods are available and quicker results may be obtained more work accrues.

Since the last committee report on this subject was rendered,¹ considerable progress has been made in assay methods, and the need for the various components in the diet of man revealed. Newer members have been added to the B complex so that a summary of each individual component with status of assay methods and needs for the diet of man seems to be in order.

THIAMIN (B₁)

Thiamin hydrochloride is a white, crystalline substance, readily soluble in water, possessing a nut-like, salty taste, and yeast-like odor. The empirical formula is C₁₂H₁₈N₄OSCl₂.

In foods and tissues it occurs in the free form and as thiamin pyrophosphate or cocarboxylose. In the latter form it functions in the living cell as a coenzyme in carbohydrate metabolism. In thiamin deficiency the metabolism of sugar is incomplete and pyruvic acid accumulates in the tissues. This gives rise to toxic symptoms, a condition which is used clinically in determining thiamin insufficiency. Many of the symptoms which have been observed in beriberi may be related to faulty carbohydrate metabolism, although it is still difficult to differentiate an uncomplicated thiamin deficiency from multiple deficiencies.

The variety of symptoms seen in man has been summarized by Spies and Williams² and by Jolliffe.³ Wilder⁴ has pointed out that the type of symptoms which develop depends to a considerable extent on the rate at which the deficiency develops, but he states that in all cases the subjects become depressed, irritable, quarrelsome, uncooperative, and fearful. An anemia of the hyperchromic type has also been

* Report of the Committee on Assay of Foods -

COMMITTEE ON ASSAY OF FOODS

Organized 1934. Published reports: *Year Books* 1935-1936, 1938-1939, 1940-1941.

described in a number of thiamin deficient patients.

The official method for the estimation of thiamin is the rat assay procedure described in the U.S.P. XII. Since our last report, both the thiochrome⁵ and yeast fermentation⁶ methods have been widely used and commented upon. Recently the thiochrome method⁷ has been adopted by the U.S.P. and sanctioned for thiamin determination in addition to the rat assay technic. The thiochrome and yeast methods have the advantage that they are quicker and can be used for substances of low thiamin content.

Because of the fact that significant amounts of thiamin may be lost during the preparation of foods, due to the ready solubility of the vitamin in water and lability to heat, it is suggested that food tables be consulted and the minimal value in these tables be used in computing the amounts of this dietary factor.

RIBOFLAVIN (B₂)

Riboflavin is an orange-yellow, crystalline compound, showing a characteristic yellow-green fluorescence in aqueous solution. The vitamin is rather heat stable, especially in acid media, but extremely labile when exposed to light. The empirical formula is C₁₇H₂₀N₄O₆. In nature riboflavin may exist as such or as riboflavin phosphate, or as a constituent of specific flavoproteins, the latter functioning as important enzymes in tissue respiration. With a deficiency of riboflavin a definite reduction in tissue concentration of the enzyme has been shown.⁸

The symptoms of riboflavin deficiency syndrome⁹ in man may be divided into three groups: A. Ocular Symptoms, B. Oral Symptoms, C. Skin Lesions.

In regard to the ocular symptoms, photophobia and interference with vision follow. With the earliest

changes seen in the eye is a growth of capillaries into the cornea. These fine capillaries cross the sclerotic and go into the cervix of the cornea. They can be seen only by the slit lamp microscope. A corneal microscope is required in order to see those vessels steadily enlarge and proliferate into the cornea until a lesion develops which can be seen grossly, and superficially may appear to be a conjunctivitis. As a lesion progresses cloudiness of the cornea develops and in some instances opaque spots or even corneal ulcers may occur. Following the use of riboflavin, these lesions in most instances have completely disappeared, and there is recovery to nearly normal vision. If the lesion is of several years' standing, more time will be required; however, remarkable improvement has taken place in a few days to a week or two.

The oral lesions are largely confined to both lips, in which there is a shiny denuded appearance, and the lips appear to be chapped in many instances. In the corner of the mouth appears a white spot which breaks down. Following this, a transverse fissure in each angle of the mouth appears. It may extend onto the face, covered with a dry, yellowish secretion. If this is removed, a raw, ulcerated crack will be found underneath. The line of closure of the lips becomes quite red and very shiny and glistening. The tongue is discolored, being described as magenta in color, or pulplish red, differing from the red tongue of niacin deficiency. Lesions of riboflavin deficiency appear in the eyes and in ulcerated lesions just inside the nares, frequently on the ears, in the folds of the body, in the groin or under the arms.

The riboflavin content of foods may be determined by measuring the growth response obtained in chicks or rats maintained on basal rations low in the vitamin, but the more rapid microbiological method of Snell and Strong¹⁰

is now finding wide application, and has been accepted by the U.S.P. as official.¹¹ Chemical methods involving measurements of fluorescence are also being used.^{12, 12a}

Riboflavin is widely distributed in plant and animal material. Liver, milk, and vegetables may be considered the best and most reliable sources in the human dietary. One serving of liver or one quart of milk adequately meets the human daily requirement.

NICOTINIC ACID (NIACIN)

Nicotinic acid occurs as white, needle-like crystals, is non-hygroscopic and stable in air, possessing a bitter taste, and has the empirical formula $C_6H_5O_2N$. The sensation of flushing and erythema of the skin often observed on administration of nicotinic acid is not produced by nicotinic acid amide. Nicotinic acid is a comparatively weak acid and its alkaline salts in solution show a slightly alkaline reaction. It is stable to autoclaving temperature when in solution and shows no loss of activity when exposed to dry heat.

Because of numerous objections to the term nicotinic acid, niacin and niacin amide have been proposed and widely accepted.

In the body niacin functions as a component of two important coenzymes, coenzyme I or cozymase, and coenzyme II, which are concerned in both glycolysis and respiration.¹³ In niacin deficiency it is possible to demonstrate a decreased cozymase content of liver and muscle tissue. The early symptoms of pellagra are dermatitis, weakness, lassitude, anorexia, mental depression, and indigestion, followed by sore and ulcerated mouth and diarrhea. However, Goldberger's classical description of pellagra (*Tice Practice of Medicine*) should not be overlooked. More detailed summary of symptoms has been recently made by Harris,¹⁴

and by Youmans.¹⁵ Spies, Walker, and Woods¹⁶ have shown that infants and children also suffer from nicotinic acid deficiency in areas where pellagra is endemic, although typical lesions are seldom seen in infancy. Nicotinic acid is now widely used in the treatment of pellagra but its use is most successful in conjunction with other vitamins and specific natural foods.

Since nicotinic acid is not required preformed in the diet of the rat, the dog, originally used by Goldberger and his coworkers for the assay of the anti-pellagra potency of foods, is the only animal that can be used with any success. Fairly accurate values can be obtained by comparing the growth response obtained by feeding a definite weight of food with that obtained after giving a standard dose of nicotinic acid.¹⁷ Chemical methods may be used on many foods and an improved method has recently been described by Dann and Handler.¹⁸

A convenient and apparently satisfactory microbiological method has been described by Snell and Wright.¹⁹ In general there is a good agreement between results obtained with the three methods except in case of liver and kidney. The values obtained with the dog assay for these materials are somewhat higher than the values obtained by chemical or microbiological methods. The best sources of nicotinic acid include liver, yeast, and lean meats.

The existence of the remaining members of the B complex is based largely upon work with animals and the use of these factors in practical nutrition is not too clearly understood. This does not mean that these newer factors are not essential in the metabolism within the body, but the corresponding deficiency diseases are not so apparent. This situation may be due to several factors: first, the recognition of the additional B vitamins is so recent that extensive clinical studies have not been

made; second, these factors are so widely distributed in a variety of foods that a serious deficiency is less likely to occur; and third, some of them at least are produced in the intestinal tract by bacteria.

PYRIDOXINE (B_6)

Two additional compounds, namely, pyridoxine and pantothenic acid, were added to the B complex between 1938 and 1940. Pyridoxine was recognized through its ability to prevent a dermatitis in rats which was observed during attempts to produce experimental pellagra in rats. It was first obtained in crystalline form in 1938, and its synthesis was described by Harris and Folkers²⁰ shortly thereafter. Pyridoxine hydrochloride is a white crystalline powder, slightly bitter in taste and odorless, possessing the following empirical formula: $C_8H_{12}O_3NCl$.

Pyridoxine deficiency in the rat has always been associated with a specific dermatitis called acrodynia by György,²¹ although it has been demonstrated²² that a lack of this vitamin may cause retarded growth without the dermatitis if ample fat is supplied in the diet. It appears²³ that linoleic acid, pyridoxine and pantothenic acid are together concerned in the prevention of dermatitis. Chick and coworkers²⁴ reported convulsions in pyridoxine deficient rats and pigs resembling epileptic fits in man. Convulsions in dogs were observed by Fouts, et al.,²⁵ and Wintrobe²⁶ has recently described convulsions in pigs on pyridoxine low diets.

A microcytic hypochromic anemia also results from a chronic pyridoxine deficiency in dogs²⁷ and pigs.²⁶ The hemoglobin and the red cells decrease progressively, the hemoglobin relatively faster than the red cells. Addition of pyridoxine causes a larger reticulocyte response, with rapid increase in hemoglobin and red cells until the normal level is attained. Rats,²⁸ pigs,²⁹ and

to some extent dogs³⁰ excrete in the urine a green pigment when on diets low in pyridoxine. Lepkovsky, et al.³¹ have now identified this compound as xanthurenic acid and have shown the compound to originate from dietary tryptophane. These and other results indicate that pyridoxine may be closely related to protein metabolism.

No clear-cut symptoms resulting from pyridoxine deficiency have been described in man. Spies, Bean, and Ashe³² have reported an additional improvement in pellagrins by giving pyridoxine after treatment with nicotinic acid, riboflavin, and thiamin. Smith and Martin³³ observed a rapid and satisfactory healing of the typical lesions of cheilosis with vitamin B_6 therapy. Although clinical treatment of such conditions as Parkinson's disease, muscular dystrophy, and paralysis agitans has been studied, the results are not definite enough to associate any one of these syndromes with specific lack of pyridoxine in the diet. Pyridoxine administration has been reported to have been used with some success in reduction in the oiliness of the skin in cases of acne.³⁴

The human requirement is unknown but animal experiments indicate that it may be about the same as thiamin, namely, 1 to 2 mg. per day. In fact, the vitamin B_6 requirement of chicks is higher than that for thiamin, 300 γ B_6 per 100 gm. ration. There appears to be no difficulty in meeting this requirement because of the wide distribution in foods. Swaminathan³⁵ found diets consumed in India to supply 3.5 to 5.0 mg. per day. Chemical methods have been used for the estimation of vitamin B_6 but the rat growth method is still the most reliable. The yeast method³⁶ has been found to give results comparable to those obtained with rats. Among the best sources of vitamin B_6 are rice bran, liver, yeast, cereals, legumes, and milk.

PANTOTHENIC ACID

Pantothenic acid in the form of calcium pantothenate became available in 1940. The term "filtrate factor" was used for several years to designate that fraction of the B complex which prevented dermatitis in chicks. Although the so-called filtrate fractions from liver extract were effective in the prevention of black tongue in dogs, pellagra in man and dermatitis in chicks, it was recognized as soon as nicotinic acid was accepted as the antipellagra factor that the activity of these fractions for the chick was not due to the nicotinic acid present but to a separate and distinct vitamin. Woolley, Waisman, and Elvehjem³⁷ and Jukes³⁸ independently demonstrated that pantothenic acid, which Williams³⁹ had shown to be a growth factor for yeast as early as 1933, was similar to the chick antidermatitis factor. The complete synthesis of calcium pantothenate which has the empirical formula $(C_9H_{10}NO_5)_2Ca$ was achieved by Stiller, et al.⁴⁰

Rats placed on diets low in pantothenic acid grow very poorly and in a few weeks develop necrosis of the adrenal cortex, a condition first described by Daft and Sebrell.⁴¹ When black or piebald rats are used, significant changes in hair pigmentation (graying) can be observed. Unna, et al.⁴² have published photographs of these fur changes in nutritional achromotrichia. Ralli and Graef⁴³ have shown that adrenalectomy will cause an increase in the deposition of melanin in the hair bulbs and follicles of rats showing graying due to filtrate factor deficiency.

Acute pantothenic acid deficiencies in dogs⁴⁴ are characterized by sudden collapse, associated with decreased blood dextrose, increased non-protein nitrogen, and lowered blood chlorides. Severe intussusception in the intestinal tract and fatty livers have also been

observed. Scudi and Hamlin⁴⁵ found a lowering of blood lipids to accompany the occurrence of fatty livers. Hughes⁴⁶ and Wintrobe⁴⁷ have described the following symptoms as occurring in pigs on a pantothenic acid deficient ration: slow growth, rough coat, loss of hair, ulcers in the intestinal tract, and a "goose stepping gait" as a result of pantothenic acid deficiency in pigs. Phillips and Engel⁴⁸ found specific neuropathologic changes in the spinal cord of chicks suffering from pantothenic acid deficiency and Wintrobe⁴⁷ has described sensory neuron degeneration.

In spite of these interesting symptoms in experimental animals, little is known about the importance of this vitamin in human nutrition. Spies and his coworkers⁴⁹ concluded from studies based largely on blood pantothenic acid values that it may be essential in human nutrition. Gordon⁵⁰ found the average daily excretion for 40 subjects to be 3.5 mg. The daily human requirement may fall within 5 to 10 mg. per day.

The pantothenic acid content of foods may be measured by growth experiments with chicks, but the microbiological methods⁵¹ are now in more general use. Liver is one of the richest sources, containing about 5 mg. per 100 gm. of fresh liver. Meats, cereals, and milk are also reliable sources. Brandaleone, et al.⁵² have recently reported that in a group of 19 elderly individuals with gray hair a significant color change was noted in only 2 individuals during intensive therapy with calcium pantothenate, para-aminobenzoic acid and brewers' yeast.

CHOLINE

Although there may be some question about the propriety of the inclusion of choline in the discussion of the vitamin B complex, the fact that choline is now added to most of the purified diets used in vitamin studies suggests that

it is logical to discuss its nutritional significance along with this group of compounds. Choline has been recognized for many years as a component part of phospholipid lecithin, but its possible need in the diet was not apparent until Best demonstrated its rôle in the prevention of fatty livers in depancreatized dogs.⁵³ The one function of choline is related to the mobilization of fatty acids in the body, since in its absence liver fat accumulates rapidly. Fatty livers in rats induced by feeding high cholesterol diets do not respond to choline treatment. The observations of duVigneaud and his collaborators⁵⁴ that the methyl groups of choline as well as those of methionine and betaine are transferable in the animal organism has led to the conclusion that another function of choline is to supply labile methyl groups. McHenry⁵⁵ states that there is evidence now that choline may function in at least three ways: to stimulate the formation of phospholipids, to make possible the production of acetyl choline, or to supply labile methyl groups.

Jukes⁵⁵ has shown that choline is one of the factors required in addition to adequate manganese to prevent slipped tendons or perosis in young turkeys. Depression of the growth rate when choline is omitted from the diet has been observed in the case of the rat by Richardson, et al.,⁵⁶ in the chick by Hegsted, et al.,⁵⁷ and in the dog by Schaefer, et al.⁵⁸

The high requirement of the young rat for choline has been stressed by Griffith⁵⁹ who previously reported fatty degeneration of the liver, hemorrhagic renal lesions, ocular hemorrhages, and regression of the thymus within ten days after the rats had been placed on a low choline but otherwise adequate diet. Cirrhosis of the liver in rats fed diets low in choline and protein has been reported by György and Goldblatt,⁶⁰ Blumberg and McCollum,⁶¹

Webster,⁶² and Lowry, et al.⁶³ The results of these studies have been summarized in *Nutrition Reviews*, Vol. 1, p. 88 (Jan.), 1943.

Fouts⁶⁴ has described fatty cirrhotic livers in dogs receiving the B vitamins in synthetic form without choline. Partial clinical improvement followed the administration of large amounts of choline, but combined administration of choline and liver extract produced more rapid improvement, although fibrosis of the liver still persisted. Some success has been reported with choline in the treatment of portal cirrhosis in man (Brown and Muettler⁶⁵ and Fleming and Snell⁶⁷), but the workers suggest that improvement is possible only when hepatic damage is not too far advanced. With the present necessary modifications in the protein and fat sources in the human diet it is well to consider the foods which can be depended upon to supply choline. Meats, cereals, vegetables, and eggs are good sources of choline. The choline content of a number of animal and plant products has recently been tabulated by Engel.⁶⁷

Reactions which have been used for the determination of choline include its oxidation to trimethylamine,⁶⁸ the formation of an insoluble complex with iodine,^{69, 70} the isolation of the chloroplatinate or chloraurate,^{71, 72} and the precipitation of choline as the reineckate.⁷³ In the latter method choline reineckate is separated from other reineckates by virtue of its insolubility in water and ethyl alcohol. When dissolved in acetone, it forms a red solution which can be measured colorimetrically. A method based on this reaction was studied in detail, either the Bausch and Lomb spectrophotometer or the Evelyn photoelectric colorimeter being used to measure color intensity. Application of the latter method to rat tissue was reported by Jacobi, et al.⁷⁴

BIOTIN

Biotin has been recognized as necessary for the growth of microorganisms for some time, and its significance in the nutrition of animals has been elucidated within the past year or so. Biotin was first isolated in 1936 by Kögl and Tonnies⁷⁵ but its complex nature and its minute concentration in natural products delayed identification of its structure. duVigneaud and coworkers⁷⁶ have recently shown that biotin has the following empirical formula: $C_{10}H_{16}O_3N_2S$. Biotin is a stable compound, resisting autoclaving with strong mineral acids, and in the form found in natural products is but slowly inactivated with strong alkali. It is readily destroyed by oxidizing agents.

It has been known for many years that a characteristic syndrome can be produced in rats fed diets containing high amounts of raw egg white. Lease, Parsons, and Kelly⁷⁷ found that the rabbit and the monkey also exhibited a typical dermatitis when fed rations containing egg whites. As early as 1933⁷⁸ Parsons concluded that the injury involved an interrelation between a positive toxicity and a relative absence of a protective factor, and a little later György named this factor vitamin H. Birch and György⁷⁹ obtained highly potent concentrates of the factor, and in 1940 duVigneaud, Melville, György, and Rose⁸⁰ suggested the identity of biotin and vitamin H.

György, Rose, Eakin, Snell, and Williams⁸¹ have now established the presence of "avidin" (an albumin) as the biotin inactivating factor in egg white. Thus it becomes apparent that egg white injury is due to the unavailability of biotin by virtue of being tied up with avidin, in which complex biotin cannot be absorbed from the intestine and is excreted in the feces. Nielsen and Elvehjem⁸² using a more complete ration than had been used in the early

work, were able to demonstrate a biotin deficiency in the rat fed 10 per cent levels of egg white. Typical symptoms of "spectacled eye," progressing to general alopecia and in the later stages the onset of a spasticity and final death of the animal, were recorded. Even the severe symptoms of spasticity were cured when excess biotin (in excess of that which unites with the avidin) was added to the diet. On the synthetic diet without the egg white these workers were unable to demonstrate any signs of biotin deficiency and it seems probable that under most conditions the rat can synthesize, through the medium of bacteria in the intestine, sufficient biotin for its requirement. Biotin deficiency has been reported in the chick without resorting to egg white diets, which seems to indicate that very limited synthesis of biotin in the intestinal tract must prevail. A typical dermatitis involving the feet was found by Hegsted, et al.⁸³ to be characteristic of the deficiency in the chick, and Patrick, et al.⁸⁴ also have noted similar dermatitis with turkeys on biotin deficient rations.

Rather definite information is available regarding the importance of biotin in human nutrition. Sydenstricker and coworkers⁸⁵ produced a deficiency in man by feeding egg white at a level which supplied 30 per cent of the calories. Symptoms of dermatitis developed as early as the 3rd and 4th weeks, and other symptoms similar to those seen in thiamin deficiency were observed. All symptoms were cured by the parenteral administration of 150–300 γ of biotin per day. Oppel⁸⁶ has shown that the biotin content of the urine is influenced by the amount in the diet. Most of the normal subjects excreted 20–50 γ per 24 hours and he was unable to find a single patient that did not excrete biotin. Sydenstricker's patients receiving egg white showed levels at low as 3.5 γ per day. Oppel

also reported that diets of average composition contained 30 to 40 γ per day or 10 to 16 γ per 100 gm. dry food. The latter value is interesting because the biotin requirement of chicks is 7 to 10 γ per 100 gm. of ration.⁸³ When the biotin content of the feces was also determined the total biotin output was 3-6 times as great as the intake from the diet. Thus there is apparently intestinal synthesis of biotin in man as well as in the rat. The intake of biotin in the diet may not be important except in special cases. It should be kept in mind, however, that a lack of some of the other B vitamins may cause deficiencies due to reduced synthesis of biotin, as well as a deficiency due to a direct lack of the vitamin in the body tissues.

Biotin can be conveniently determined by use of microbiologic methods of assay in which responses in yeast growth (Snell, Eakin, and Williams⁸⁷) or acid production by *Lactobacillus casei* (Shull, Hutchings, and Peterson⁸⁸) are measured. Biotin is almost ubiquitous in distribution, but liver, kidney, yeast, and egg yolk are the chief sources. It is to be emphasized that in most tissues biotin is present in a "bound" state in which it cannot be extracted by hot water, and autolysis or acid hydrolysis must be employed to realize the true concentration of biotin in these instances.

INOSITOL

The significance of inositol in animal nutrition was first recognized through the use of the mouse. Eastcott showed as early as 1928 that inositol would stimulate the growth of yeast. In 1940 Norris and Hauschildt⁸⁹ found that mice failed to grow on a synthetic diet containing the known members of the B complex. In addition to lack of growth, the animals showed loss of hair and scaly dandruff. Liver and yeast supplements produced normal animals.

Woolley⁹⁰ described a similar condition and identified the factor in the yeast and liver as inositol. Further studies⁹¹ indicated that some of the animals without inositol showed spontaneous cures. Cultures from the intestinal tract of the mice showing the spontaneous recovery yielded organisms which would synthesize much more inositol than cultures taken from the tract of mice that remained hairless. This synthesis was not observed when pantothenic acid was absent from the diet. Since no one has been able to demonstrate the need for inositol in the diet of growing rats, there is apparently sufficient synthesis by the bacteria to meet the requirement. Whether this is true in man remains to be determined.

Inositol can be determined in tissues and foods by using a microbiologic assay employing a specific strain of yeast as the test organism.⁹² By this method of determination, Williams and his coworkers⁹³ have made large numbers of assays on various rat and beef tissues and found spleen, heart, kidney, brain, thyroid, and testes to be especially high in inositol. As previously mentioned, inositol in the form of phytin is present in large amounts distributed throughout the plant kingdom; cereal brans and seeds are exceptionally good sources. No work has been done on the possible significance of inositol in human nutrition.

PARA-AMINOBENZOIC ACID

Para-Aminobenzoic acid was first described as a bacterial growth factor by Rubbo and Gillespie⁹⁴ and Ansbacher⁹⁵ concluded it was a vitamin in 1941. Sieve⁹⁶ has used it as an achromotrichia factor. The fact that this compound is widely distributed in nature suggests that it may be an important vitamin. In the chick it can partially compensate for the lack of liver extract factors when fed at high levels. Thus it may have an indirect

effect by altering the synthesis of other factors in the tract. Martin⁹⁷ has reported similar results in the rat and suggests that it may have such an effect in man.

OTHER FACTORS

In order to study still other possible members of the B complex it has been necessary to use rats receiving sulfaguanidine or succinyl sulfathiazole, or chicks and monkeys on synthetic diets containing the nine B vitamins mentioned so far.

If 0.5 per cent sulfaguanidine or succinyl sulfathiazole is added to a synthetic diet containing thiamin, riboflavin, nicotinic acid, pyridoxine, pantothenic acid, and choline and fed to rats, the rate of growth is greatly reduced and the prothrombin time of the blood is increased. The addition of liver extract to this ration gives optimum growth and normal clotting time of the blood.⁹⁸ The liver extract can be replaced by a folic acid concentrate and biotin.⁹⁹ Thus the rat requires biotin and one or more factors in the folic acid concentrate, but under normal conditions these factors are produced by the intestinal bacteria. Gant, et al.¹⁰⁰ have shown a reduction in the coliform organisms in the tract of rats upon feeding succinyl sulfathiazole. Spicer, Daft, Sebrell, and Ashburn¹⁰¹ have reported a consistent development of a leucopenia and an agranulocytosis in rats receiving sulfaguanidine or succinyl sulfathiazole in synthetic rations. The total number of leucocytes dropped from a normal of 10,000 to less than 1,000 in severe cases.

Chicks fed a modified synthetic diet plus the synthetic B vitamins, including biotin and inositol, not only fail to grow but show very poor feathering and a rather extensive anemia.¹⁰² All three deficiencies can be counteracted by adding 2 per cent liver extract or 5 per cent yeast to the diet and all the

activity can be concentrated in crude folic acid preparations from these foods. Similarly monkeys fail on synthetic diets but live and develop normally if liver extract, grass juice powder, or a crude folic acid preparation is used.¹⁰³

VITAMIN M

When given a diet deficient in the B vitamins, rhesus monkeys develop a syndrome characterized by anemia, leucopenia, oral lesions, diarrhea, and susceptibility to bacillary dysentery.¹⁰⁴⁻¹¹⁴ The syndrome cannot be prevented or cured by any combination of the now commercially available pure vitamins, but can be prevented, and sometimes cured, by yeast, fresh liver, and certain crude liver extracts. The term "vitamin M" was proposed for the nutritional factor.¹⁰⁶ There is evidence that xanthopterin may partially or completely protect the monkey against this nutritional cytopenia when fed in combination with the other available B vitamins.¹¹⁵ It has also been reported that "folic acid" concentrates are active in correcting the anemia and leucopenia in this experimental condition in the monkey.^{112, 113} Since "folic acid" concentrates appear to contain xanthopterin¹¹⁶ it is not clear whether this activity is due to the "folic acid" as such, or to the xanthopterin, or to a combination of the two. There is some evidence of a biological nature for a relationship between "folic acid" and xanthopterin.¹¹⁷ Until the exact relationship between "folic acid," xanthopterin and "vitamin M" is clarified it will not be possible to use the microbiological method for "folic acid"¹¹⁸ as a measure of "vitamin M."

At the present time the only specific assay method for "vitamin M" is the bio-assay based upon the protection of the monkey against nutritional cytopenia, or the cure of nu-

tritional cytopenia. The protective method is laborious as it is necessary to protect a monkey for approximately a year in order to demonstrate the effectiveness of a supplement. The curative technic is not always satisfactory, as the monkeys enter an irreversible phase if the deficiency is allowed to progress too far.

It is evident therefore that the remaining members of the B complex can be concentrated in a crude folic acid concentrate. Most of these preparations have been made according to the procedure described by Hutchings, Bohonos, and Peterson.¹¹⁹ These workers used the *Lactobacillus casei* for the assay of the activity. Mitchell, Snell, and Williams¹²⁰ used spinach as the source of their factor and the *Streptococcus lactis* as the test organism. They named the factor folic acid and found a rather pure concentrate to stimulate the growth of *L. casei* as well as *S. lactis*. For some time the two factors were considered to be the same, but very recently Keresztesy, Rickes, and Stokes¹²¹ isolated a pure substance which is effective for *S. lactis* but is inactive for *L. casei* and they suggest that it is not folic acid. Pfiffner, et al.¹²² have obtained from liver a compound in pure form which is active in preventing anemia¹²³ in chicks on purified diets. These workers have retained the term B₆ for this compound and they suggest that it may be identical with both the *L. casei* and *S. lactis* factors. In light of the above report this is not possible. The question which remains therefore is: are the two bacterial growth factors related to the factors needed by the rat, chick and monkey? Briggs, et al.¹²⁴ have clearly demonstrated that the chick requires two factors which are separate and distinct from the *S. lactis* factor. These two factors have been temporarily called vitamins B₁₀ and B₁₁. It is more likely that the factor needed by

rats fed the sulfonamides and by monkeys fed synthetic diets is related to the *L. casei* factor, especially since the factor corrects an anemia in chicks. The final isolation of these factors will do much to give us a complete picture of the remaining B vitamins.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted.

Medicine and the War—*Edited by William H. Taliaferro. Chicago: University of Chicago Press, 1943. 193 pp. Price, \$2.00.*

This admirable series of ten popular lectures was delivered in the spring of 1943 by members of the faculty of the Division of the Biological Sciences of the University of Chicago under the sponsorship of the Charles R. Walgreen Foundation for the Study of American Institutions. The historical introduction to war medicine is by Dr. Arno B. Luckhardt, Professor of Physiology. The subjects of Food, Chemotherapy, Malaria, Insects, Shock and Blood Substitutes, Aviation Medicine, Brain Injuries, Psychiatric Disorders, and Chemical Warfare are covered by Professors Paul R. Cannon, E. M. K. Geiling, William H. Taliaferro, Clay G. Huff, Alexander Brunschweig, Henry T. Rickets, A. Earl Walker, David Slight and Franklin C. McLean. The essays are intended to promote a wider dissemination among the general public and the medical profession of basic information concerning recent advances in war medicine. They cover the subjects briefly, although authoritatively, and can be recommended to public health workers who are not experts in these fields of medicine.

GEORGE BAEHR

The Organization of Permanent Nation-wide Anti-Aedes aegypti Measures in Brazil—*By F. L. Soper, D. B. Wilson, S. Lima, and W. Sá Antunes. New York: Rockefeller Foundation, 1943. 137 pp.*

This monograph is a highly detailed account of the organization instituted by the Brazilian Government and the Rockefeller Foundation for the control

of the *Aedes aegypti* mosquito in Brazil, stressing the particular problems encountered both in rural and urban areas, and those peculiar to this species of mosquito. It would seem very desirable that the southern states here and the other South American republics should follow this leadership and adopt similar measures.

The most significant fact revealed is the remarkable results obtained by the authors. For example, the incidence of houses with aedes in Natal was reduced from 10 per cent in 1931 to zero in 1934. This, of course, will result in lowered yellow fever and dengue fever rates.

The organization of the text could have been planned better. In the body of the work too many forms for inspectors, diagrams of flags, etc., are included. These could have been placed to more advantage in an appendix along with the intricate details of filling them out. The duties and responsibilities of the personnel are fully explained, but the sequence of this material is broken by the forms.

Only one fault of omission can be readily found, namely, that there is nowhere any reference made as to the training of the inspectors who are the backbone of the organization.

The problems of mosquito control and eradication are most vital at the present time, therefore this book should prove of great value to public health officials who are responsible for this type of work.

WILSON G. SMILLIE

Fundamentals of Personal Hygiene—*By Walter W. Krueger. (4th ed.) Philadelphia: Saunders, 1944. 315 pp., ill. Price, \$1.75.*

The preface to the fourth edition of

this book states that the aim of the book is to "motivate the student to formulate a rational health program and thus to acquire the art of living healthfully." How far health teaching and reading books can help in such motivation, the reviewer does not know.

This book was definitely not written with the viewpoint of the youngster in mind. It neglects the natural self-interest of growing up and getting something out of life. It "tells" more than it teaches. The factual material presented is quite detailed regarding physical fitness. Very little can be learned about vision and hearing. The same is true regarding items on community health.

The chapters on the mouth, the skin, the feet, and especially health fads, fancies, and follies are adequately covered. There are two excellent chapters on "Health of the Mind," and one on "Hygienic Aspects of Sex," but what a title.

There are at least two serious mistakes, both in the chapter on "Sunlight and Health." Ultra-violet rays are described as a factor in preventing tooth decay and, an even more dangerous statement, "It is now believed by some investigators that sunlight may prevent death from cancer." Since when do investigators merely "believe"? They should *know*. Theories on prevention and cure should be omitted.

It is beyond our understanding why in the list of "Topics for Oral or Written Discussion" included in the chapter on "Health of the Mind," was the question, "Would a fifth freedom; namely, the freedom of individual enterprise, be of value for mental health *as well as for other reasons?*" (Italics ours.)

Illustrations are supposed to help the reader to understand the text. Unfortunately, most of the illustrations are meaningless, inadequate, and poorly

labeled. There are very few original drawings or photographs. Most of the pictorial material is second hand and from commercial sources.

The bibliography is excellent and the book can be recommended for use by teachers but, in the interest of the mental hygiene of students, we hope it is not scheduled as required reading.

BRUNO GEBHARD

Maurice Arthus' *Philosophy of Scientific Investigation: Preface to De l'Anaphylaxie a l'Immunité, Paris, 1921. Translated from the French, with an Introduction by Henry E. Sigerist. Foreword by Warfield T. Longcope. Baltimore: Johns Hopkins Press, 1943. 26 pp. Price, \$.75.*

Here in only seventeen pages is epitomized the full spirit of research. It is a translation of the preface of Arthus' famous *De l'Anaphylaxie a l'Immunité*. We owe a real debt of gratitude to Dr. W. T. Longcope, Professor of Medicine, and to Dr. Henry E. Sigerist, Professor of the History of Medicine at Johns Hopkins, for recognizing the scientific and literary value of this gem. Their ardent sponsorship and Sigerist's colorful translation provide its very appropriate setting.

With deft precision, Arthus outlines the principles of all experimental methods: "Observe facts, conceive a hypothesis, determine its value through . . . experiments . . . give the interpretation . . . and ascertain the excellence of this interpretation through strict criticism; generalize the results experimentally. . . ." He gives a stern rebuke to those who follow the primrose path: "Seek facts and classify them . . . and you will be the workmen of science. Conceive or accept theories . . . and you will be their politicians."

The paper is not written negatively. Arthus shows that pitfalls are to be avoided by honesty, clarity, precision, and self criticism. The final exhorta-

tion to independence and originality is downright evangelical.

This is a perfect gift to the young person who contemplates or has entered upon a scientific career. Arthus does not emanate the glamor of the pseudo-scientist but in this booklet provides an eternal inspiration and beacon. Sigerist most aptly describes Arthus's service to the neophyte scientist: "His honesty, his fanatical devotion to science, his insistence on originality and last but not least his method, still the most promising one today, will provide them with guidance and will renew their faith in the dark hours of discouragement through which every researcher must go."

This attractive presentation by the Johns Hopkins Press is also sturdy. It is a booklet to be cherished and preserved.

CHARLES EDWARD SMITH

Understanding Juvenile Delinquency—*Children's Bureau Publication 300.* 52 pp. Price, \$.10.

Controlling Juvenile Delinquency—*Children's Bureau Publication 301.* 28 pp. Price, \$.10. *Washington: U. S. Department of Labor, Children's Bureau, 1943.*

These helpful pamphlets complete a series of three issued by the U. S. Children's Bureau on the recommendation of the Children's Bureau Commission on Children in Wartime. As the war has progressed the problem of juvenile delinquency has become more and more acute. Communities throughout the country have been attempting to control juvenile delinquency with very little success in the present emergency. It is first necessary to have clearly in mind what juvenile delinquency really is, and the factors which contribute to it. These pamphlets meet both of these demands.

It is pointed out that "In wartime, as in peacetime, juvenile delinquency

results from our failure to satisfy the basic needs of children and youth—the need for security and for opportunity for growth and development."

The factors contributing to delinquency are well set forth in this series and the community resources which may be tapped are emphasized in the section on Prevention and Treatment. The pamphlets are practical rather than theoretical and deserve wide circulation at this critical time.

RICHARD A. BOLT

Health and Hygiene—By Lloyd Ackerman. *Lancaster, Pa.: Jaques Cattell Press, 1943.* 895 pp. Price, \$5.00.

The author has attempted to provide a book that appeals to mature minds in all walks of life. He believes that institutions of higher learning err in offering hygiene to freshmen, in that they are unprepared to understand the problems of health and disease and to grasp the possibilities of obtaining and maintaining health.

The field of personal health is well covered, except that in the industries. Unusual emphasis is given to the rôle of the mental and emotional aspects of health. In fact, the reader is likely to come to the conclusion that these are the major factors in obtaining and maintaining health.

After introductory chapters on the hygienic concept and the causative agents in health, disease, and death, the author treats of the evolution of health concepts and practices, and evaluates these. Next follow chapters on parasitism and hypersensitiveness, nutrition, emotions and the intellect, and the hygiene of the sexual life. Lastly he treats of the exogenous poisons and physical agents in their relation to health.

The author is to be commended for presenting clearly both sides of controversial questions. The frequent use of

technical terms that are not familiar to the general reader leads to the suggestion that a glossary be added to this excellent treatise.

The chapter on the evaluation of health procedures should be read widely by those who are skeptical of the methods of science.

EDWARD C. SCHEIDER

Allergy Anaphylaxis and Immunotherapy—Basic Principles and Practice—*By Brct Ratner. Baltimore: Williams & Wilkins, 1943. 834 pp. Price, \$8.50.*

The book is described in the subtitle, "A treatise presenting the fundamental principles and practice governing the use of antisera, vaccines, toxoids, blood transfusions, blood substitutes and sulfonamides, in the prevention and treatment of infectious diseases and of the allergic phenomena resulting from their use."

In Book I, the practitioner, who makes use of these prophylactic and therapeutic agents will find lucid and informative discussions of their nature, source, methods of preparation and of administration, in forty-odd infections. This part of the book should be a useful supplement to the chapters on infectious diseases in the textbooks of medicine and of the pediatrics.

Book II contains an excellent comprehensive, thoughtful, and practical discussion of serum allergy in all its phases. Drug allergy and transfusion reactions are covered briefly but adequately. There are few physicians, allergists excepted, who will not find this portion of the book illuminating and useful.

There is little in Book III which is not found in the recent textbooks of allergy.

On the whole, the book is worth while. It is well planned and well presented. A few minor criticisms are in order, however. The studies of

Cooke, Loveless, Hampton, Sherman, *et al.*, of the thermostable or blocking antibody should certainly have been discussed. The studies of Karelitz and Glorig on serum sickness may have appeared too late (August, 1942), for inclusion. The author's arteriolar spasm theory of wheal formation has been discredited. Book III has more academic than practical interest. None of these detract significantly from the value of the book. OSCAR SWINEFORD, JR.

Ohio River Pollution Survey—Final Report to the Ohio River Committee. Federal Security Agency, U. S. Public Health Service, Cincinnati, Ohio, 1942. 793 pp.

The final report of the U. S. Public Health Service has just been made to the Ohio River Committee. This committee was appointed by the Secretary of War under authority granted by the River and Harbor Act of August 26, 1937, to supervise a study of Pollution in the Ohio River Basin. The committee consisted of a representative of the Corps of Engineers, United States Army, Brigadier General T. M. Robins (first representative was Brigadier General Max C. Tyler); a member of the United States Public Health Service, R. E. Tarbett; and a non-government expert, Dr. Abel Wolman. The survey was designed to ascertain what pollution substances are being deposited, directly or indirectly, and the sources and extent of such deposits, with a view to determining the most feasible method of correcting and eliminating the pollution.

In the Public Health Service report to the committee, separate statements are made on the findings for the main Ohio River, the minor tributary basins, and on 19 major tributary basins. The report includes 6 supplements, outlining in some detail the following phases of the study: Collection of Data on Sources of Pollution, Laboratory, Or-

ganization and Methods, Acid Mine Drainage, Industrial Waste Guides, Epidemiological Studies, Biological Studies.

The report is especially significant because it is the first pollution study of a complete large river basin (including all of its tributaries) in the United States, covering some 204,000 square miles. A technical staff of 95 engineers, chemists, and bacteriologists, together with personnel from the various state health departments and the Tennessee Valley Authority, spent over 4 years in the collection and analyses of the data. These studies are valuable not only because of the completeness of the data collected on the Ohio River Basin, but because the technics used will serve for many years as a guide for similar and comparable studies of other river basins. The Corps of Engineers has also made its report to the committee and a joint report with recommendations and cost estimates for comprehensive control measures has been made by the committee to Congress as instructed in the Act. The complete report will be available later in printed form.

ALFRED H. FLETCHER

Health for the Having—A Handbook for Physical Fitness—By William R. P. Emerson, M.D. New York: Macmillan, 1944. 146 pp. Price, \$1.75.

The author dedicated this pocket size book of 146 pages "to the thousands of our youth whose greatest disappointment has been their rejection for active duty in all branches of our armed forces because of physical unfitness." Since our future existence depends upon man power, Dr. Emerson emphasizes the necessity of improving physical and mental stamina. In 15 chapters he offers advice on how this can be done.

The physician can correct physical defects, but the individual only can correct faulty health habits. He states

that "after middle life our chances of reaching old age are no greater than 50 or 100 years ago." Therefore he explains what steps are necessary for individuals to take in order to prevent crippling degenerative diseases and also to attain and maintain high buoyant health.

Discussion centers on such subjects as physical fitness examination, weight, blood pressure, health habits, starving amidst plenty, overwork, time budgeting, the American school system and health, and longevity—14 pages in the appendix give tables of various kinds. This is a book for lay adults. It touches briefly on many health subjects of common interest.

W. W. PETER

Physical Fitness for Boys—By Ben Miller, Karl W. Bookwalter, and George E. Schlafer. New York: Barnes, 1943. 457 pp. Price, \$3.00.

Physical fitness teachers and supervisors are provided with a useful directing instrument in this book. Provision for details of planning and evaluation of programs and of student progress are well indicated. Emphasis is placed on need for continuity of physical fitness programs in student development. Activities from which selection may be made for adequate programs under differing circumstances are offered. Details of administration, including a realistic proposal of record forms, represent a contribution.

General legal and moral responsibilities of the school in physical fitness are brought forward, for instance, in school accidents. Suggestions for qualifications of staff, improvement of staff, maintenance of morale, evaluation of instruction, and program promotion should be found useful.

While basic individual health is mentioned as a requisite in these programs, the text does not cover methods of securing the coöperation of public health,

medical, dental, nursing, and other health groups. Health evaluation of individuals and groups as a concomitant of physical fitness is not provided. Disease prevention and health education in the program are inadequately treated. Provisions for handling those physically inadequate are not detailed. More adequate treatment of problems, such as fatigue and nutrition, in relation to physical efficiency, might well have been expected. Methodology and plans for coordination of school programs with community and industrial recreation organizations might have been included.

F. M. HEMPHILL

A Guide to Practical Nutrition—
Edited by Michael G. Wohl, M.D., and John H. Willard, M.D. Sponsored by the Committee on Nutrition and Deficiency Diseases of the Philadelphia County Medical Society, Philadelphia, Pa., 1943. 98 pp. Distributed to physicians.

The Committee on Nutrition and Deficiency Diseases of the Philadelphia County Medical Society has prepared for the medical profession a convincingly written 98 page book which is not just another recital of nutrition fundamentals. The points covered show the result of careful discrimination whereby only facts which apply directly to the everyday medical problems are included, with special emphasis on those subclinical conditions which are now recognized to be just as important as a definite pathological deficiency disorder.

Throughout the text is an appeal to every physician to use this newer knowledge of nutrition to educate the public to appreciate the importance of proper nutrition as a means of promoting the physical improvement of the individual for the welfare of America. "A Guide to Practical Nutrition is to

be considered part of a program of public health education—not as a complete coverage of the field of nutrition."

Dr. Morris Fishbein says in the Introduction: "Until adequate knowledge of deficiency diseases and scientific nutrition becomes the property of all members of the medical profession, the utmost that can be accomplished in this field will not be accomplished."

The book consists of 13 papers written by 12 different people, all but two of whom are physicians. One of these physicians who wrote the section on Nutritional Aspects of Dental Disease also is a dentist. Although the subject is addressed to the physician, the book will be of value to nurses, nutritionists, teachers of home economics, and others who have the background to enable them to interpret its scientific terms. LUCY H. GILLET

Expectantly Yours—A Book for Expectant Mothers and Prospective Fathers—
By Mario A. Castallo, M.D., and Audrey Walz. New York: Macmillan, 1943. 110 pp. Price, \$1.75.

Among many books for expectant mothers and fathers, *Expectantly Yours* is unique in two ways: it gives more background, setting, and general orientation to maternity than is usual in such small space, and it is written definitely for the well-read, sensitive patient who can profit by information on a higher level of knowledge than is usually offered. The authors use such phrases as "chemical affinity," "salivation," "involution," and touch on such topics as sex determination, syphilis and gonorrhea, forceps delivery, and caudal anesthesia.

Withal, this work is practical, scientifically sound and direct, and it is so entertainingly written that it will not be put down.

DOROTHY DEMING

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Sour Public Health Note—In 1943, Mr. and Mrs. United States and most of the little U. S.'ers smoked 257 billion (note the "b" please) cigarettes. The additional billions sent tax free to our soldiers are not counted. Per capita the annual figure is 1,877, and each year it increases hugely. Please complete your own annotation.

ANON. Tobacco Consumption in the United States. *J.A.M.A.* 125, 3:213 (May 20), 1944.

Germicidal Mists—Maintenance of glycol vapors in adequate concentration is possible in large spaces, but some means of air agitation is desirable, and a minimum relative humidity of 40 per cent is necessary.

BRIGG, E., *et al.* The Use of Glycol Vapors for Bacterial Control in Large Spaces. *Am. J. M. Sc.* 207, 3:361 (Mar.), 1944.

Hospitals, Health Departments and Health—If health facilities—preventive and curative—are to be distributed equitably, there is need, in each country, for a national health service with a central, or federal, agency responsible for all aspects of national hygiene. How hospitals might fit into this scheme is the nub of this paper. Though the arguments are persuasive, there will be some who will agree only that there should be a national health service in every country—except the U.S.A.

DRAPER, W. F. Hospitals in the Public Health Panorama. *Pub. Health Rep.* 59, 16:513 (Apr. 21), 1944.

Pudding's Proof—In Iceland there is an epidemic of whooping cough about every 7 years. Almost every

susceptible child catches it, then the conflagration dies out for lack of fuel. In the face of the latest visitation 5,000 Reykjavik children were quickly vaccinated. Percentage-wise this is what happened: compared to controls nearly 6 times as many of the protected children escaped altogether; in each group half the children had mild infections (no whoop); mediumly severe infections were twice as common among the controls; and gravely severe infections more than double.

DUNGAL, N., *et al.* Vaccination Against Whooping Cough. *J.A.M.A.* 125, 3:200 (May 20), 1944.

Gonorrhea Should Go—Another note reminding us that penicillin really does cure gonorrhea—if given in sufficient dosage. This is good news for the v.d. controllers, for the drug is now to be available for civilian use too, apparently.

FERGUSON, C., and BUCHHOLTZ, M. Penicillin Therapy of Gonorrhea in Men. *J.A.M.A.* 125, 1:22 (May 6), 1944.

Department of Stray Facts—Miscellaneous information to add to your little store of knowledge: When rabbits are injected with diphtheric toxoid incorporated in lanolin, antitoxin formation is enhanced and prolonged, as compared with plain toxoid. Paraffin oil enhances antibody formation against typhoid bacilli and killed tubercle bacilli have an additional synergistic effect. There isn't much you can do with this intelligence at the moment.

FREUND, J., and BONANTO, M. V. The Effect of Paraffin Oil, Lanolin-like Substances and Killed Tubercle Bacilli on Immunization with Diphtheric Toxoid and *Bact. Typhosum*. *J. Immunol.* 48, 5:325 (May), 1944.

More Evidence That Generalized Nursing Is Practical—For twenty years Berkeley (Calif.) has carried on a unified, generalized nursing program. This report tells about the school, public health, and visiting nursing services which each of the staff members performs. The plan is fundamentally sound and provides the community with the most efficient service at the lowest possible cost, concludes the writer.

GILCREST, E. W. A Unified Service of Long Standing. *Pub. Health Nurs.* 36, 4:164 (Apr.), 1944.

Alcoholism as a Public Health Problem—Part one gives promise that this series will be unusually interesting and provocative. It is a dissertation on present-day scientific research in the field of alcohol studies, the outgrowth of a good deal of pseudo-science undertaken to prove the wishful beliefs of pŕos or antis. What I like about the paper is its tone—it is written with a reasonableness that is most reassuring.

JELLINEK, E. M. Alcohol Research—Theoretical and Practical. *Pub. Health Nurs.* 36, 5:223 (May), 1944.

Uses of Cancer Reports—Is the cancer reporting game worth the statistical candle in respect to the light it sheds? The arguments against reporting are well known and are frequently aired. There seems to be a good case for reporting in this account of three years' experience in New York State.

LEVIN, M. P. Cancer Reporting in New York State. *New York J. Med.* 44, 8:880 (Apr. 15), 1944.

"Better Health for the People"—What sort of black magic, do you suppose, boils up through that wholly imaginary line marking the Canadian-American border which permits the reasonable men on the north side, who govern the affairs of the Canadian medical association, to think and talk

about public medical services with equanimity, while equally reasonable men south of the line, who decide the affairs of our medical association, see red whenever the word social medicine is mentioned? The paper prompting this impertinent speculation is about integrated health and medical services in Canada.

LEWIS, D. S., and JACKSON, F. W. The Integration of Preventive and Curative Medicine in Health Insurance. *Canad. Pub. Health J.* 35, 3:99 (Mar.), 1944.

Healthy Skepticism about Nutrition—A Doubting Thomas *sp. Canadensis* looks critically at the spurious accuracy which seems to be the basis for a good many of the nutritional standards set up by certain Canadian authorities. Where, he asks, are the data to support the recommendation that a man must have 75 mg. of ascorbic acid, but a woman only 70 mg.? That is only a single sample. One wonders if our 'straight-faced, American pronouncements have been scrutinized with equal objectivity.

McHENRY, E. W. Recent Trends in Nutrition. *Canad. Pub. Health J.* 35, 4:154 (Apr.), 1944.

About a Neglected Step-child—Time was when the educational movie enjoyed a prominent place in the affections of us sanitarians. With certain notable exceptions among our health agencies, it is safe to assume that health movies are being neglected today, yet American military authorities and Canadian and British civil authorities are making increasing use of training and documentary films. This paper suggests what may be wrong with our unsatisfactory health "squeakies."

NICHTENHAUSER, A. Planned Health Film Production. *J. Health & Phys. Educ.* 15, 5:251 (May), 1944.

Tomorrow's Defenses against Disease—Pointing out the interdependence of military and civilian public

hygiene and the steps being taken to secure a healthy citizenry in support of a healthy soldiery, the Surgeon General suggests that the future of medicine may be in the hands of the thousands of physicians now in the military and naval services. Concentrated there are the youngsters who have the greatest stake in that future. Having become used to the best facilities of modern group medicine they may be loath to return to a "horse and buggy" medical economy.

PARRAN, T. Teamwork on the Health Front. *Mil. Surgeon*. 94, 2:76 (Feb.), 1944.

Antidote for Rose-colored Spectacles—We have started toward the greatest epidemic of gonorrhea that our country has ever experienced, says this man who sees all sides of this problem and warns against the easy assumption of cure after a brief course of sulfonamides.

PELOUZE, P. S. Gonorrhea: The Epidemic We Face. *Ven. Dis. Inform.* 25, 3:76 (Mar.), 1944.

Enormous in Scope and Complex in Character—Eleven papers presenting up-to-the-minute solutions for problems in industrial health. Tuberculosis, factory sanitation, nutrition, eyesight conservation, rehabilitation,

and vocational training are some of the timely topics discussed in this symposium, which every interested health worker quite naturally will read.

SEGER, S. J., *et al.* Sixth Annual Congress on Industrial Health. *J.A.M.A.* 125, 4:239 (May 27), 1944.

Without Benefit of Kenny—So much has been written about the superiorities of the Kenny treatment, that there will be interest in the outcome of some recent Chicago cases in which orthodox methods were employed. Roughly, three-quarters of the patients had no, or barely detectible, residual weakness at the end of care.

SHERMAN, M. S. The Natural Course of Poliomyelitis. *J.A.M.A.* 125, 2:99 (May 13), 1944.

Worms, *et al.*—From the parasite-infested corners of the earth our military personnel will return with a cumulative load of tropical diseases unequalled since the days of slave-trading, cheerfully prophesies this writer. What to do about protozoal diseases, and nematode, cestode, and trematode infestations is the timely burden of this paper.

WRIGHT, W. H. Present and Post-War Health Problems in Connection with Parasites. *Science*. 99, 2568:207 (Mar. 17), 1944.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Charles F. Atkinson, M.D., Court House, Traverse City, Mich., Director, Grand Traverse-Leelanau Health Dept.
 Douglas B. Avison, M.D., D.P.H., 293 Ethel St., Kelowna, B. C., Canada, Director, Okanagan Valley Health Unit
 Benjamin W. Black, M.D., 2701 14th Ave., Oakland 6, Calif., Alameda County Medical Director
 Alvin R. Christopherson, D.M.D., 805 Tribune Bldg., Salt Lake City, Utah, Member, State Board of Health
 William D. Cutsungavich, M.D., Holden, Alta., Canada, Medical Officer of Health, Holden Health Unit
 Abe J. Davis, M.D., Richmond County Health Dept., Augusta, Ga., Commissioner of Health
 George M. Downard, Ph.C., 315 U. S. Custom House, Portland 9, Ore., Inspector, U. S. Food and Drug Administration
 John R. Francella, M.D., 227 E. Chestnut St., Coatesville, Pa., Health Officer
 Dudley Glen-Campbell, M.B., D.P.H., Tuberculosis Clinic, Kingston, Jamaica, B.W.I., Asst. Tuberculosis Officer, Jamaica Government
 Morris Gordon, M.D., 3224 Grand Concourse, New York, N. Y., Tuberculosis Clinician, Bureau of Tuberculosis, Dept. of Health
 Carl E. Hill, M.D., 5248 Yonge St., Willowdale, Ont., Canada, Medical Officer of Health, Township of North York
 Bernard Hochfelder, M.D., 809 Pere Marquette Bldg., New Orleans 12, La., Physician
 John B. Hozier, M.D., M.P.H., 8 Kilsyth Terrace, Brookline, Mass., Surgeon, U. S. Public Health Service; Director, Genito-Infectious Division, Massachusetts Dept. of Public Health
 James E. Johnson, M.D., Health Center, 708 Lexington Ave., Fort Smith, Ark., Director, City-County Health Unit
 Harold M. Johnston, M.B., M.P.H., Island Medical Office, Kingston, Jamaica, B.W.I., Malaria Officer, Government of Jamaica
 Herbert S. Lawrence, D.P.H., Port Maria, Jamaica, B.W.I., Health Officer, St. Mary Government Medical Service
 Hyacinth Lightbourne, M.B., D.P.H., 187 Mountain View Ave., Liguanea, Jamaica, B.W.I., Medical Officer of Health, Jamaica Medical Service

John A. Lindquist, M.D., 300 S. 7th St., City Hall, Springfield, Ill., Director of Health
 Albert F. Litzengruber, M.D., 411 Pearl St., Boyne City, Mich., Director, Dist. No. 3, Michigan Dept. of Health
 Capt. Stephen K. Molnar, M.C., 17010 Tireman, Detroit 10, Mich., Sanitation Officer
 Percival C. Murray, M.D., M.P.H., Island Medical Office, Kingston, Jamaica, B.W.I., Medical Officer of Health, Government Medical Service
 Alfred A. Peat, M.B., M.P.H., Spanish Town, Jamaica, B.W.I., Medical Officer of Health, Jamaica Government
 Dr. Miguel Silva-Martinez, Estacion de Adiestramiento Sanitario, Coatepec, Vera Cruz, Mexico, Asst. Director, Health Training Center
 Tennyson B. Sinclair, M.D., D.P.H., Port Antonio, Jamaica, B.W.I., Health Officer, Island Medical Dept.
 Edward J. Valentine, M.B., D.P.H., Falmouth, Jamaica, B.W.I., Medical Officer of Health, Jamaica Government Medical Service
 H. Garner Wright, M.D., County Court House, Bellingham, Wash., Health Officer, Whatcom County Health Dept.
 Otis W. Yeager, M.D., 14th Ave. and Lake St., San Francisco, Calif., Medical Officer, Plague Suppressive Measures, U. S. Public Health Service

Laboratory Section

Josephine Alsworth, 440 Winton St., Jackson, Miss., Bacteriologist, State Board of Health
 Leonard E. Arnold, M.D., D.P.H., 4 Ripon Road, Cross Roads, Jamaica, B.W.I., Asst. Government Pathologist and Bacteriologist, Government of Jamaica
 Lenora J. Burditt, 5911 Grand Ave., Riverside, Calif., Student, University of California
 Major Harry E. Carnes, M.C., Exec. Officer, U. S. Army Medical Laboratory
 Virgil F. Chapman, Health Dept., City Hall, Dubuque, Iowa, Sanitary Bacteriologist
 William E. Clapper, Ph.D., University of Utah, Salt Lake City, Utah, Asst. Professor of Bacteriology
 Anne Craig, 1339 North State, Jackson, Miss., Medical Technician, State Board of Health
 Cornelia E. Dingle, 306 Riverway, Boston 15, Mass., Bacteriologist, State Health Dept.
 Richard Eglinton, 1179 Main St., Hartford

- 1, Conn., Chief Microbiologist, Bureau of Laboratories, State Dept. of Health
- Kelly H. Eldredge, 1862 Lake St., Salt Lake City, Utah, Teacher of Bacteriology, University of Utah
- June F. Gaffney, 1865 Clay St., San Francisco 9, Calif., Laboratory Technician, Southern Pacific General Hosp.
- Lt. Milton Goldin, Sn.C., Laboratory Officer, U. S. Army Hospital
- Martha K. Hohl, 1834 Delaware St., Berkeley 3, Calif., Bacteriologist, Div. of Labs., State Dept. of Health
- Kathleen Hussey, Ph.D., 600 W. 168th St., New York, N. Y., Research Assoc. in Parasitology, DeLamar Institute of Public Health
- Barbara J. Klever, 1341 S. Parton St., Santa Ana, Calif., Laboratory Technician, Orange County Health Dept.
- Barbara Lang, Box 36, Poquonock, Conn., Sanitary Chemist, State Dept. of Health
- Thomas L. Martin, Ph.D., 20 E. 9 North, Provo, Utah, Prof. of Bacteriology, Brigham Young University
- Martha Michelbacher, Ph.G., 1701 Thousand Oaks Blvd., Berkeley 6, Calif., Bacteriologist, State Dept. of Public Health
- Rosemary L. Noakes, 1307 Second Ave., San Francisco 22, Calif., Laboratory Technician, G. W. Hooper Foundation for Medical Research
- Jose E. Ortiz, St. Lukes Hospital, Ponce, Puerto Rico, Medical Technologist
- Mrs. Quay DeBure Rice, 154 Mills Ave., Spartanburg, S. C., Medical Technician, Laboratory, Station Hospital, Camp Croft
- Lillian Rodofsky, 27 Summer St., Revere, Mass., Asst. in Bacteriology Dept., Tufts Medical School, Boston
- Mary E. Rymer, 751 E. Platte Ave., Colorado Springs, Colo., City Chemist and Bacteriologist
- Lt. Benjamin Shapiro, Sn.C., 101st General Hospital, Camp Grant, Ill., Laboratory Officer
- Mildred B. Talley, 909 Wood Ave., Waco, Tex., Junior Serologist, Waco McLennon County Health Unit Lab.

Aurelia B. Potts, R.N., Nashville, Tenn., Elected Member 1928, Elected Fellow 1934, Public Health Education Section

Dr. Rafael Silva, Mexico City, Mexico, Elected Member 1930, Health Officers Section

CLIFFORD C. YOUNG, D.P.H.

Dr. C. C. Young, for many years Director of Laboratories, Michigan State Health Department, died on June 5.

Dr. Young was born in Kansas, and educated at the University of Rochester and the University of Kansas. He received the degree of Doctor of Public Health from the University of Michigan in 1924. His vision and energy have placed the Michigan State Health Department Laboratories among the

most outstanding in the country.

Dr. Young was elected to membership in the Association in 1912. He was a charter Fellow. He served three terms on the Governing Council, was Chairman of the Laboratory Section in 1928, and Chairman of the Committee on Meetings and Publications from 1930 to 1935. He was a member of the Executive Board at the time of his death, having been elected for a three year term in 1941.

CLOSING DATE FOR SUBMITTING FELLOWSHIP APPLICATIONS

Members who may be interested in applying for Fellowship in the A.P.H.A. are hereby advised that Fellowship applications should be received by the Central Office not later than August 1, to insure consideration at the Second Wartime Public Health Conference and 73rd Annual Business Meeting to be held in New York October 3 to 5.

EMPLOYMENT SERVICE

The Association Employment Service seeks to bring to the attention of appointing officers the names of qualified public health personnel and to act as a clearinghouse on employment. This is a service of the Association conducted without expense to the employer or employee.

From the registry of persons available, selected announcements are published from time to time. Appointing officers may obtain lists of all registrants on request.

Address all correspondence to the Employment Service, American Public Health Association, 1790 Broadway, New York 19, N. Y.

NEWS FROM THE FIELD

MICHIGAN STATE COUNCIL OF HEALTH

At the first meeting of the Michigan State Council of Health held since the appointment of William DeKleine, M.D., as State Commissioner of Health, Henry F. Vaughan, Dr.P.H., Dean, School of Public Health, University of Michigan, was reelected President of the Council, a position which Dr. Vaughan has held for the past five years. The other members of the Council include Harold E. Wisner, M.D., Detroit; John A. Galbo, D.D.S., Detroit; Wesley H. Mast, M.D., Petoskey; Charles L. Hess, M.D., Bay City.

PUBLIC HEALTH ASSOCIATION OF NEW YORK CITY

The Eighth Annual Meeting of the Public Health Association of New York City was held on May 17.

The proceedings opened with a session in the afternoon on "Debits and Credits in Public Health in War-time in Our City." The three speakers were: Dr. Leona Baumgartner, Director, Bureau of Child Hygiene, Department of Health of the City of New York; Bailey B. Burritt, Chairman, Executive Council, Community Service Society; and Dr. Theodore Rosenthal, Director, Bureau of Social Hygiene, Department of Health of the City of New York.

At the dinner session, the speaker of the evening was Lt. Col. Paul H. Stevenson, Senior Surgeon (R), U. S. Public Health Service, who has recently returned from Burma. His topic was "Expanding Horizons."

Dr. John L. Rice, on behalf of the American Public Health Association,

gave a brief report on the plans for the Second Wartime Conference of the A.P.H.A. to be held in October at Hotel Pennsylvania in New York. He read a message from Dr. Reginald M. Atwater, Executive Secretary of the A.P.H.A., urging all the local members to attend the sessions.

The officers elected to serve until the Annual Meeting in 1945, were:

President—Leverett D. Bristol, M.D.
First Vice-President—Sol Pincus, C.E.
Second Vice-President—John L. Rice, M.D.
Secretary-Treasurer—Frank Kiernan
New members of the Executive Board:

GEORGE F. CAMPANA, M.D.,† has been appointed Acting State Health Officer to succeed F. J. HILL, M.D.,† who has resigned as State Health Officer for North Dakota to accept the city health officership for Minneapolis, Minn. Dr. Campana has served as Director of the Division of Preventable Diseases of the North Dakota Department of Health since June, 1943, coming to Bismarck from New Rochelle, N. Y., where he was Acting City Health Officer.

JOHN H. GILPIN, M.D., Cheboygan, Mich., has been appointed District Health Officer of Cheboygan, Presque Isle, Montmorency, and Alpena Counties.

FRANK J. HILL, M.D., M.P.H.,† who for about three years has been State Health Officer of Bismarck, N. D., has resigned to accept appointment as City Health Commissioner of Minneapolis, Minn., succeeding F. E. HARRINGTON, M.D.,† who is retiring.

HUGO V. HULLERMAN, M.D., M.S. P.H.,* has been appointed Secretary of the Council on Professional Practice of the American Hospital Association, Washington, D. C. Dr. Hullerman was formerly Chief of the Division of Maternal and Child Health of the Illinois Department of Public Health, Springfield, Ill.

ALBERT T. PETERSON, formerly Director, Field Service with the Middle-

CORRECTION

In the JOURNAL for April, 1944, pages 335 and 347 in listing the members of the Commission on Acute Respiratory Diseases, inadvertently the name of Dr. A. E. Feller was omitted. The members are: Drs. John H. Dingle, Director, T. J. Abernethy, G. F.

* Fellow A.P.H.A.

† Member A.P.H.A.

sex County Tuberculosis and Health League, New Brunswick, N. J., has recently accepted a position with the Denver Tuberculosis Society, Denver, Colo., as Health Education Secretary. Mr. Peterson is a graduate of Northwestern University and has had college teaching experience in the Midwest and in the East.

MARY E. SOULES, M.D., M.P.H.,† Director of Maternal and Child Hygiene for the North Dakota State Department of Health, Bismarck, N. D., has resigned.

BUELL H. VAN LEUVEN, M.D.,† Traverse City, Mich., has been appointed Health Director of Chippewa County, Mich.

JOHN P. WALSH, M.D.,† Wheaton, Ill., Health Officer of DuPage County, has been transferred to supervise a five county health unit with headquarters at Dixon.

Eastern States

JOHN HALL,* Freehold, N. J., recently Director of Health Education with the U. S. Public Health Service has been appointed Field Assistant with the American Social Hygiene As-

sociation, New York, N. Y. His first assignment is to the 8th Army Service Command, Texas, Oklahoma, New Mexico, Arkansas and Louisiana.

EMMA M. VARNERIN, M.D., has been appointed Assistant District Health Officer of the Division of Communicable Disease, State Department of Health, Boston, Mass.

Southern States

MARGARET H. ERVIN,† formerly with the Bellemead Coal Company, Sabine, W. Va., has accepted an appointment to the staff of the Laird Memorial Hospital, Montgomery, W. Va., as a clinical technician.

JAMES A. HAYNE, M.D.,* Columbia, S. C., State Health Officer for 33 years, has resigned.

BALLARD NORWOOD, JR., M.D.,† Oxford, N. C., has resigned as Health Officer of Granville County, N. C., to enter private practice.

BRIGADIER GENERAL JAMES STEVENS SIMMONS,* U. S. Army, Chief of the Preventive Medicine Service, Office of the Surgeon General, U. S. Army, Washington, D. C., has been elected as a member of the Council on Industrial Health of the American Medical Association.

Number 8

The Coöperative Health Program of the American Republics

GEORGE C. DUNHAM, M.D., Dr.P.H., F.A.P.H.A.

Major General, U. S. Army, Executive Vice-President, Institute of Inter-American Affairs, and Assistant Coördinator of the Office of the Coördinator of Inter-American Affairs, Washington, D. C.

THE Inter - American Cooperative Health Service in the other American republics is a practical illustration of a united approach to the health problems of a neighborhood. The initiation of this extensive public health campaign was motivated by the recognized importance of concentrated measures for health protection throughout the Western Hemisphere. When extensive application lags behind well established knowledge, contagion can wax rampant and unrestrained. Preventable and curable sickness and death have in the past, and can still successfully hamper war effort and establish barriers in restraint of trade and economic development. With these well proven facts clearly in mind, 18 of the other American republics have embarked upon a joint program with the United States, to marshal forces against the insidious attack of fatal and debilitating enemies to well-being and efficiency.

There is ample evidence that the interchange of scientific knowledge in-

cluding medical work in foreign countries is one of the most important factors in cementing international friendship. Public health work can serve not only to protect the people in other countries but is also of paramount importance for safeguarding our own population.

The Inter - American Cooperative Health Services were organized to assist and implement the good neighbor policy at a time when the threat of German conquest was most serious and every possible means had to be used to combat the powerful Axis influence in the Americas. The Japanese invasions of countries in the Far East cut off practically all of our important sources of rubber, tin, cinchona and other vital products. We had to depend upon the other American republics not only for supplies of important materials but also for coöperation in the defense of strategic areas.

The provision of medical and public health services for persons directly engaged in the war effort is an important

function of the Cooperative Health Services. The control of malaria has received major emphasis. General activities include such features as physical examinations, vaccination, emergency medical care, the distribution of medicines, and the provision and supervision of elementary sanitation. In this fashion an attempt has been made to improve the health and efficiency of the workers in rubber areas, on cinchona and sisal plantations, in the tin mines, and in the rich, diversified mining regions of Brazil, as well as highway and railroad workers in several of the countries. Sanitation and other public health measures have been intensified around air bases and in areas where our armed forces are stationed.

In addition to this work, which is largely of emergency and temporary character, the Cooperative Health Services are planned to supplement and extend existing activities and to introduce new patterns in the provision of a sound plan for immediate and long-term disease control.

In accordance with the prescribed directives for the extension of public health, the campaign includes increased opportunity for the utilization of therapeutic and preventive measures through the construction, equipping, and operation of hospitals, dispensaries, clinics, and health centers; fundamental and widespread activities for improved water supply systems, for sewage disposal, insect abatement, and other sanitary measures; training of professional workers in their specialties, and education of lay groups for the provision and practice of healthful living; and direction and evaluation of control measures through field and laboratory investigation. These are the activities being developed to realize the objectives expressed in January, 1942, at the third meeting of Ministers of Foreign Affairs of the American Republics at Rio de Janeiro.

The delegates of all 21 American republics agreed that:

The defense of the Western Hemisphere required the mobilization of the vital forces, human and material, of the American republics and

Adequate health and sanitary measures constitute an essential contribution in safeguarding the defensive powers and the ability to resist aggression of the peoples of the American republics.

Resolutions were adopted advocating the extension of inter-American co-operation in a plan designed to further well-being and strengthen the bonds between the nations of the Western Hemisphere. The Congress of the United States voted an appropriation and authorized the Coordinator to set up a corporate entity, the Institute of Inter-American Affairs, with power of attorney to administer funds and execute cooperative agreements with the other American republics.

The Health and Sanitation Division of the Office of the Coordinator of Inter-American Affairs was established in February, 1942, as one specialized branch of an organization that includes many other operations in informational and economic fields.

Close liaison is maintained with numerous governmental and civilian agencies. These include the Pan American Sanitary Bureau, the National Research Council, the Bureau of Medicine and Surgery of the Navy, the Office of the Surgeon General of the Army, the Army Medical School and the Army Medical Museum, the United States Public Health Service, the International Health Division of the Rockefeller Foundation, the Foreign Economic Administration, inter-American committees of professional associations, schools of public health, medical schools and universities.

The work now in progress in 18 of the Latin American republics is entirely on a cooperative basis. The funds

appropriated by the Congress of the United States for this purpose are administered through the Institute of Inter-American Affairs. This incorporated body has made a grant to each of the republics now cooperating.

The republic wishing to participate also contributes its share of funds, materials, and personnel. The direction of activities and the disbursement of the combined funds is determined by the joint agreement of a Chief of Party from the Institute and an appointee of the national government. The Chief of Party is the head of the cooperative organization known in most of the countries as the SCISP (Servicio Cooperativo Inter-Americano de Salud Publica), which is an integral part of the national department of health. In many places, the Service is continuing and extending activities previously initiated by the health departments, while in other countries, long needed programs are being introduced.

Directive, consultant, and technical personnel for the field parties are provided by both the division of health and sanitation and the health department of the republic, but the organizations are composed for the most part of nationals as professional and technical employees and other local workers. On January 1, 1944, there were about 200 members of field parties from the United States and 13,000 nationals of the other republics employed in the program, of whom some 600 were physicians, nurses, sanitary engineers, or other professional personnel. Practical nurses, sanitary inspectors, technicians, administrative personnel, and office employees numbered about 2,400 and 10,000 were skilled or unskilled workmen.

PREVENTIVE AND THERAPEUTIC SERVICES

Hospital or dispensary construction is under way or completed in 10 of the

republics. In some instances this has consisted of repairs or additions to existing buildings. In others, badly needed new facilities are being constructed and equipped. Operation of infirmaries for Brazilian migrants is an important part of this program. In Ecuador, which has the largest hospital program, existing structures are being improved or replaced to provide more adequate in-patient care in 16 general hospitals, and two isolation, two maternity, a children's, and a tuberculosis hospital. Leprosaria are under construction in Paraguay and Peru.

In addition to buildings, other services are being provided for improved in-patient medical care such as sanitary facilities and surgical, laboratory, and x-ray equipment.

Health centers, clinics, and medical posts are of major importance in this plan for controlling the spread of disease. Over 100 such stations are now under construction or in operation throughout Latin America.

In El Salvador, the National Department of Health and the Service are cooperating in the development and expansion of health centers throughout the Republic. Four existing full-time centers in the principal cities now provide immunization, maternal and child health services, tuberculosis and venereal disease control, dental hygiene and laboratory facilities, with headquarters for nurses, sanitary inspectors, and other offices. The Health Department and the Service are providing permanent structures to replace the inadequate buildings now in use.

Fourteen centers have been maintained on a part-time basis by the National Health Department, and have made available certain health services such as vaccination and vital statistics. An attempt is now being made to extend the program as it functions in the full-time health units and to make maternal and child health and venereal

disease control services available on a part-time basis to 12 cities of from 5,000 to 15,000 inhabitants. The physicians in charge of the part-time work received a short intensive course in public health, provided chiefly by the staff of the Health Department with the assistance of a few of the outstanding physicians of San Salvador. The Service provided the allowance to each doctor for travel, subsistence and salary during the period of instruction. The entire cost of the operation of these health centers is being borne by the National Department of Health, with the exception of a limited supply of equipment and drugs necessary for the maintenance of the venereal disease program.

The Health Department has also provided doctors, sanitary inspectors, and full-time visiting nurses. The office space and certain supplies are in some instances being maintained by the local municipality.

The health center in Asuncion, Paraguay, was designed to provide clinic space in the building for tuberculosis, syphilis, leprosy, skin diseases, prenatal and maternal hygiene, clinics and a general medical diagnostic clinic to serve as a referral center. A diagnostic laboratory, x-ray rooms, pharmacy, and auditorium, demonstration center, and a waiting room are also on the ground floor. Offices of the Ministry of Health and the Director of Hygiene and branch departments are to be on the second floor.

Some medical care is being provided throughout the Amazon Valley by means of launches, and to workers on the Pan American Highway through mobile dispensaries. In the Republic of Honduras, five clinics and health centers operated by the Service reported 1,939 patients treated during a single month. By far the majority of the patients had malaria, with 887 cases reported, and intestinal parasitism

was next in order of importance, with 276 cases.

SANITATION

The extension of environmental sanitation has its major emphasis on improved water supply and sewage disposal, with programs under way in 8 republics. In El Salvador, surveys of existing sanitary conditions within the city of San Salvador were undertaken to consider the problems of water supply, sewage disposal, garbage disposal, markets and slaughterhouses, in addition to health center activities and communicable disease control. Improvements in the water system were recognized as urgent, and three storage tanks have been completed, with provision for the chlorination of the entire water supply of the city. An improved and increased water supply is being provided for the city of Zacatecoluca. Sewerage systems are being constructed for San Miguel and Santa Tecla.

A country-wide community sanitation project is under way in Haiti. Facilities for excreta disposal, construction and sanitation of a rural market, and a slum clearance project have been completed at Port-au-Prince. Work is proceeding on similar projects in other communities, including small water supply systems, construction of public toilets, installation of school privies and septic tanks. In other republics the work also covers jail sanitation, garbage collection and disposal, and special projects involving supervision of sanitation at air bases and labor camps.

Near the upper end of the Rio Doce Valley at Itabira, State of Minas Gerais, Brazil, is probably the world's largest deposit of high-grade iron ore. There are also large deposits of manganese, mica, quartz, and other minerals in this valley. These resources cannot be fully developed without an extensive health and sanitation program to prevent and treat malaria and other diseases. Com-

panhia do Vale do Rio Doce has been formed with the Brazilian and United States Governments providing equal shares of the capital. The company will develop mineral resources and reconstruct the railway between Itabira and Vitoria, an Atlantic coast town in the State of Espirito Santo.

An agreement was entered into with the Companhia Vale do Rio Doce of Brazil and the Service for advice as to location and arrangement of labor camps and the supply and supervision of sanitary facilities.

The railroad is being relocated through a very low swampy region where malaria is endemic. Labor crews of 200 to 500 persons are provided for each unit of 10 kilometers of the right-of-way. About 27,000 persons, including workers and members of their families, are benefited by these activities of the Service. Epidemiological investigations and extensive malaria control measures are in operation in the camps. Sanitary supervision of the camps has included water supply and housing as main problems, with excreta disposal provided by bored hole latrines.

The sanitary engineering activities related to permanent mosquito control represent the most widespread type of environmental sanitation. Drainage, ditching and filling, and the construction of dikes and tide gates, as well as temporary control measures, have been initiated in 13 of the republics.

EDUCATIONAL MEASURES

The provision of training programs for professional workers in these republics has as its primary objectives the encouragement of specialization in medical and public health fields, to make available the services of an increasingly large and valuable group of well trained experts throughout the Americas. The Pan American Sanitary Bureau and the Rockefeller Founda-

tion have done pioneer work in this field. The Division of Health and Sanitation is supplementing their activities by extending opportunities to increasing numbers of physicians, nurses, sanitary engineers, and other public health personnel for training in their specialties. A total of 142 persons from the other republics had already come to the United States by January 1, 1944, under the auspices of this program. Their courses of study include training in schools of public health, medical schools, hospitals, and other institutions and in urban and rural health organizations, and travel grants to observe the functions and activities of public health departments and other organizations in the United States.

A recent development is an inter-country training program which provides for limited periods of training, especially in field work, at selected places within the other republics.

Another important phase of the training program is the provision of nurses' training or organization of schools of nursing in Bolivia, Brazil, Colombia, Ecuador, El Salvador, Nicaragua, Paraguay, and Peru, with provision of or addition to buildings, equipment, and staffing. Together with this long-term coöperative program, short courses in practical nursing are also provided.

Short courses of instruction are being given locally in most of the countries to their own physicians in charge of full-time health centers, to sanitary inspectors and medical technicians. The courses are given by the staff of the coöperative program in collaboration with local health department or hospital staffs.

A proposed health center and field training station in the village of Boca del Rio, Mexico, will have the usual activities of a health unit for the welfare of the people and, in addition, will

offer intensive field training for physicians.

Health education of the lay public is recognized as essential to the recognition and popular support of the public health program. This is a function of all medical and public health activity through medical care, public health centers, and special disease control programs. Organized campaigns are under way or are being planned in almost all of the republics. In Paraguay, for example, the Department of Sanitary Education has arranged a series of regular radio programs on syphilis, tuberculosis and cancer, and a special "Health Week" series. Health films have been shown at educational meetings in schools, workers' centers, and factories. Articles are sent to the newspaper at regular intervals and a *Sanitary Bulletin* and special pamphlets are distributed to selected groups throughout the country. About 6,000 posters are displayed in public places.

The important contributions of laboratory and field investigation are being increased by the provision of facilities and personnel training in many of the cooperating republics, as well as by the use of services provided either by local existing laboratories or by those operated as a part of the cooperative program. Public health laboratories are being constructed in Bolivia, Brazil, Colombia, Ecuador, and Paraguay. Better diagnostic facilities will be available as a result of much of the hospital construction and, in many areas, as an important function of the cooperative health centers.

During May, 1943, a central nutrition laboratory for Colombia was established in Bogota. Analyses of salt, milk, fruit, vegetables, soil, and water have been made. The salt and water studies, indicating absence of iodine, are being used as the basis of a campaign against endemic goiter. The Institute of Epidemiology of Bogota

has this nutrition research as one phase of its activities, which also include experimental work on typhus, bartonellosis, malaria, and rickettsiosis.

The laboratory work at health centers in Colombia has included blood counts; smears for rickettsia, blood parasites, and gonococci; serological reactions; and fecal, urine, and sputum examinations.

Extensive laboratory investigations are being conducted in Brazil where the staff, equipment, and buildings of the Malaria Control Service of the Northeast and of the Institut de Patologia Experimental Evandro Chagas, in Belem, were assigned to the Amazon Project of the Cooperative Service by the Brazilian government. The staff includes a trained entomologist, physicians, a microscopist, a photographer, technicians, and field inspectors. The activities of the Amazon Valley Laboratory include the investigation of malaria, filariasis, leishmaniasis and trypanosomiasis, in addition to routine laboratory work and teaching. Malaria studies have included species identification and the collection of parasitic and splenic indices. In the Belem area, the prevalence of filariasis in the human population and the infection rate in the intermediate host and vector have been studied. A survey is in progress to determine the species of *Phlebotomus* and their distribution in the Amazon Valley, and xenodiagnosis is being used in the study of trypanosomiasis. Routine laboratory work performed in conjunction with the Service activities has included bacteriological examination of clinical specimens, analyses of drinking water, blood matching, and stool and urine examinations.

CAMPAIGN AGAINST SPECIFIC DISEASES

Malaria—A primary objective in this crusade is the subjugation of malaria. The debilitation and destruction caused by this outstanding scourge are un-

equalled in severity and extent. Throughout most of the other American republics relentless war is being waged upon the mosquito and the parasites which it disseminates. Specific projects are in most instances preceded by entomological and engineering surveys; studies on incidence by obtaining splenic and parasitic indices; and the proportionate distribution of the species of malaria plasmodia. Engineering activities include the construction of dikes and tide gates, drainage, ditching, filling and spraying. Treatment and resultant control consist in the distribution of millions of tablets of atabrine from health centers and medical posts.

Coöperative malaria control has been initiated in Bolivia, Brazil, Colombia, Ecuador, Haiti, Peru, and Venezuela; and in each of the Central American republics, with activities concentrated along the route of the Pan American Highway. In Panama, the health and sanitation program consists entirely of some 50 projects devoted exclusively to suppressing the mosquito.

In the Amazon Valley, the emphasis is at present upon medical care for migrants and rubber workers, entailing the distribution of atabrine from infirmaries, medical posts, and dispensaries throughout the Valley. Mosquito control projects are likewise in operation, for with the overthrow of the heretofore triumphant and undisputed reign of the *Anopheles*, a vast region of potential resources should become available.

Extensive malaria control activities are being practised in many areas, but as illustrative of the program in a particular country, Honduras may be chosen as an example. Project No. 1, now completed, consisted of a reconnaissance survey in 18 principal cities of the republic for the purpose of securing an index of the amount of malaria in the country and to make certain initial technical studies in some of

these cities to determine the practicability of instituting permanent malaria control. An initial sanitary survey was made of each town. Splenic indices and blood smears were obtained from representative groups of school children, mosquito surveys were conducted, and some topographical studies were made. Tables and maps were prepared showing mosquito and malaria distribution and rainfall data. The survey results were used in the concentration of attention on areas of primary importance.

A 22 acre lagoon near Amapala was found to constitute a prolific mosquito breeding area. The water is being cleared of matted growth and the borders freed of vegetation, with maintenance operations to be continued by the public works department of the municipality.

Temporary control was initiated in Choluteca with the location of breeding places and their periodic treatment with oil or Paris green. Permanent malaria control drainage initiated in this town is providing open drain channels to care for the run-off of rain water and thereby help eliminate mosquito-breeding water pools.

The surface water drainage system of the town of La Ceiba is being improved by re-laying certain portions of the system and by increasing its capacity through larger and more adequate size pipe.

Plans are being drafted for permanent malaria control operations in most of the towns, which have a combined population of over 100,000 persons to be directly benefited by these operations.

Tegucigalpa was omitted from the general survey as most of the information sought is already known for the capital city. As a result of engineering studies in certain sections of the city, a project is being devoted to oiling, or dusting, of stagnant pools in outstanding breeding areas and routine collec-

tion of larvae and adult mosquitoes. A permanent control project is being drafted for some areas.

In addition to the engineering activities, other public health services and medical care, including diagnosis and medical treatment, have been made available for the control of malaria among workers throughout the rubber producing area and along the Pan American Highway.

Health centers at Amapala, Choluteca, Nacaome, San Marcos de Colon, Tegucigalpa, and Trujillo distribute atabrine and information on the means of spread and of protection against malaria.

Tuberculosis—Tuberculosis is of serious import throughout the other American Republics, with mortality rates that in some areas are reported to exceed 500 per 100,000 population. A special concern of the health centers everywhere, and in some instances, of concentrated campaigns, tuberculosis control activities consist of case finding, education, study of contacts, provision of visiting nurses, and organization of record systems, supplemented by the construction of tuberculosis sanatoria.

According to the vital statistics collected by the National Department of Health, tuberculosis is one of the leading causes of death in Nicaragua. The department has an Administrative Division for Tuberculosis, but has been hampered by lack of facilities. The Service is starting a tuberculosis control project to provide the Department of Health with additional space and equipment. Health education and nursing personnel are being furnished through other Service projects, and facilities will include a mobile x-ray unit for case finding and follow-up clinics; x-ray equipment for taking of 4" x 5" films for the tuberculosis clinic of the Department of Health; and conversion of tuberculosis pavilions at the San Pablo Hospital, Bluefields.

Venereal Disease—The most extensive project involving venereal disease control is that conducted along the United States-Mexico border, in cooperation with the United States Public Health Service and the Pan American Sanitary Bureau. The Office of the Coordinator coöperated in this program by allocating the funds for the establishment and maintenance of the campaign as one of the many important special projects financed by this office. The activities include the awarding of special fellowships for study of venereal disease control; the organization and supervision of an educational campaign against venereal disease; and organization, supervision, and assistance in the execution of prophylactic measures. Enthusiastic participation by the Mexican Government is an important feature of the program.

In the Panama Canal Zone administrative services have been provided, including the establishment and maintenance of a central office of the Division of Venereal Disease Control of the Health Department of the Canal Zone.

At the request of the naval authorities, a coöperative project was initiated at Corinto, Nicaragua, for the maintenance of a clinic, at first primarily for examination of prostitutes, but since extended in the direction of a local venereal disease control program.

In health centers, dispensaries, and clinics throughout the republics emphasis is being placed upon the control of venereal disease. As a part of the health center program in El Salvador, for example, the attendant-physicians in 12 part-time health centers were provided with supplies of drugs for the maintenance of venereal disease clinics, and a strenuous attempt is being made to follow up contacts and bring them into the clinic for treatment.

Intestinal Parasites—Parasitic infestation is extremely widespread throughout the other Americas and it has been

estimated that, in some areas, 90 to 100 per cent of the population harbor intestinal parasites. The provision of safe water supplies and sewage disposal is a major means of combating this health hazard. These measures are supplemented by services directed principally through health centers and dispensaries for surveys of infested areas, health education programs, and mass treatment of infected persons.

At Tingo Maria Hospital, in Tingo Maria, Peru, a program has been developed for an intensive campaign against hookworm. Attempts will be made to examine the entire population of selected areas for hookworms, distribute and supervise the administration of hexylresorcinol, stimulate and perhaps subsidize in a small degree the construction of sanitary privies, and endeavor to make general the wearing of shoes.

Yaws—In Colombia, the Pacific Coast Sanitary Campaign has as its special objective the control of infectious diseases in the swampy lowlands along the southern part of the Pacific Coast where four health centers have been established. The treatment of yaws is a major feature of the program now being extended to areas further north in which the incidence of yaws is also high.

An important activity of the anti-yaws campaign in Haiti is the training of local personnel to assist in the organization and operation of rural treatment centers. According to Health Department records, there are estimated to be about 300,000 cases of yaws in Haiti. Attendance at the first yaws clinic opened at Gressier increased from 158 in March, 1943, to 917 in April, 2,181 in May, and 11,915 in October.

Typhus—Typhus fever study and control are under way in Colombia, El Salvador, and Guatemala. Plans have also been made for a cooperative

project with the Pan American Sanitary Bureau for work in southern Bolivia. A research project on typhus fever in El Salvador is concerned with the isolation of the virus from rats as well as from patients. In Colombia, laboratory study of arthropods and blood specimens has been extended, and a roving commission is conducting experimental vaccinations. In Guatemala, epidemiological studies are being made to determine the prevalence of this disease with concomitant measures for control, including immunization of contacts and elimination of insect vectors. A serologist from the Army Medical School Laboratory spent two months in Guatemala City doing laboratory work during the preliminary survey and training technicians.

During October, 1943, a typhus outbreak occurred in a textile factory engaged in work directly associated with the war effort. Approximately 40 deaths had occurred from typhus during July and August, among a population of 1,000 factory workers and their families. In an attempt to control further spread of the disease, the owners of the factory agreed to hire a full-time medical officer and the necessary number of assistants, as well as to provide all the medical supplies. The National Health Department agreed to provide supervision and consultative medical services, and the Service agreed to provide personnel for teaching the medical staff and sanitary inspectors employed by the factory.

Plague—In Bolivia and Ecuador, plague control measures have been undertaken in conjunction with the Pan American Sanitary Bureau and local health authorities.

Work began in February, 1943, in an area in the south central part of Bolivia where bubonic plague has been endemic for a number of years, and several serious localized epidemics have occurred. Large numbers of domestic

rats and their ectoparasites are being studied. Sylvatic plague is also reported to be present.

Suppressive measures in Ecuador are being extended along the Guayaquil-Quito Railway and particularly in the endemic rural area of the Province of Chimborazo. The campaign is being directed toward the extermination of rats, fleas, and guinea pigs, for it is felt that evidence points definitely to the guinea pig as an intermediate host between rat and man. Trapping, poisoning, cyano gas flame throwers, and insecticide sprays are being used, and rat and flea killing measures have been repeated two or three times in most of the area.

Bartonellosis—The service in Colombia inaugurated, in March, 1943, a campaign against bartonellosis. Studies are being conducted for the investigation of the epidemiology, the mode of transmission, of the disease and the possible development of a vaccine for prevention.

SPECIAL PROJECTS

The Institute of Inter-American Affairs has also authorized the allocation of funds for a number of special projects. These are not under the supervision of the Services but constitute separate activities, many of them under the immediate direction of the Pan American Sanitary Bureau, such as fellowships in military medicine; additional public health nurses requested by the other American republics; the visit of medical and public health experts from the other Americas to the meeting of the American Public Health Association, and to institutions and cities of special interest; the collection of biostatistical and epidemiological information from the southern republics; and onchocerciasis control in Guatemala and Mexico.

SUMMARY

The work of the Inter-American

coöperative health program is directed toward the control of the spread of infectious disease and toward the promotion of health by preventive and therapeutic measures. The extension of international health work is fundamental in a world where diplomatic exchange of notes, political treaties, and the opening of channels of commerce and transportation have long been recognized as necessary for the progress of civilization. The Inter-American health program has already proved to be an efficient means of cementing the friendship and coöperation that were absolutely essential to the Western Hemisphere at the outbreak of the present world war. All the republics have profited by the exchange of ideas, personnel, and materials with which this campaign has been related. A pattern has been established for the introduction and extension of health measures that are of importance not only to the persons immediately concerned but also over a far-reaching area.

The threat of disease is especially ominous at this time, for the waging of war has always been attended by marked increase in the prevalence of contagion among civilians and soldiers alike. The present program operates not only toward the alleviation of debilitation and death at those places where specific measures are provided, but also toward the prevention of disease spread among distant as well as nearby population groups.

In some areas, the other Americas have spent millions of dollars and employed thousands of persons on communicable disease programs which have ultimately benefited the United States. The people of this continent are greatly indebted to the successful campaigns initiated in Brazil for the eradication of *Anopheles gambiae*, imported from Africa and an especially dangerous vector of malaria. The measures directed against the *Aedes aegypti* in

Brazil and Colombia have aided in the solution of a problem which might have resulted in devastation of our own shores and necessitated expensive measures against yellow fever. Our present coöperative services are waging a war to prevent the dissemination of disease from one country to another.

Disease has through the ages followed the lines of transportation. With the increasing frequency and rapidity of travel, especially in cargo and passenger planes, previously adequate quarantine restrictions are weakened not only by hitch-hiking insect vectors but also by the conveyance of regular passengers who have become infected and are deposited in unprotected communities during an incubation period that terminates only subsequent to arrival.

With the provision of preventive and therapeutic measures, hitherto disease-

ridden areas become more accessible for cultivation and development. Such measures, more than any other, can serve to stimulate the production of some important tropical materials that in the past have been largely limited to the Far East.

The coöperative effort is now serving in the interests of increased efficiency for war products and, with opportunity for development, there will come the growing purchasing power which is the necessary basis for the extension of commerce and support of trade. By the exchange of students, the provision of health center and hospital services, widespread health education, the improvement of environmental sanitation, and the use of specific control measures, a coöperative effort is being directed toward the more efficient preservation and utilization of human and other resources.

Wartime Nutrition in England as a Public Health Problem*

HUGH M. SINCLAIR, M.D.

Fellow of Magdalen College, Oxford; University Demonstrator in Biochemistry, Oxford; Director, Oxford Nutrition Survey, Oxford, England

AT this meeting two years ago Sir Wilson Jameson, the Chief Medical Officer of the Ministry of Health, told you a little about the nutritional surveys that are being made in England by the Oxford Nutrition Survey. I should like first to expand what he said and then to make some broad generalizations about the conduct of such surveys. I feel encouraged to do this because those of us who work in the field of human nutrition have usually been so engrossed in cultivating our own small part of it that we have rarely put down our tools and stepped back to see what crops or even weeds we are growing, and I have been permitted at least to put down my tools during the ten weeks in which I have had the privilege of visiting nutritional projects in this country and in Canada at the invitation of The Rockefeller Foundation.

Let me first, then, tell you very briefly of the development and organization of the Oxford Nutrition Survey. Its first seeds were sown in the summer of 1940, and they suddenly sprouted and rapidly grew a year later. At that bad period of the war in England our food policy was designed, as it still is, to save shipping for military purposes by keeping the population on

the lowest diet compatible with health. It was obviously important, therefore, to watch the nutriture of the population, and that could only be done by making nutritional surveys. In May, 1941, we started to make such surveys with the backing of the Ministries of Health and Food, endeavoring to include so far as our resources permitted all reasonable methods. Obviously that was slow and laborious, but it was necessary to try all methods because of the uncertainty—to my mind—of most of the suggested ways of assessing the state of nutrition. However, it was clear that if we had a central organization making surveys in and around Oxford to test, develop, and apply such methods, it would be possible also to have a mobile team that could go out from Oxford around the country and make quick surveys using the methods that had been found to prove most useful.

We now have such an organization in Oxford, making detailed surveys for public health purposes and carrying out essential research; and we have a mobile team of three persons which spends about two months in any one town and examines the members of upward of 70 families in that time. The primary purpose of the whole organization has been to discover the incidence, cause, severity, and distribution of malnutrition in England.

* Presented before the Food and Nutrition Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 14, 1943.

THE DEFICIENCIES REVEALED

The main survey has now examined about 4,000 subjects. Probably the most serious problem in England is ascorbic acid; dietary intakes of about 20 mg. a day are quite common; and, being without citrus fruits, our main dietary sources are potatoes and cooked vegetables. There is also some evidence of deficiency of vitamin A, iron, and calcium, and possibly of animal protein and of fat; but there is little or no evidence of deficiency of total protein, thiamin, or riboflavin. We see much gingivitis and follicular hyperkeratosis, and a great deal of dental caries; but there is very little corneal vascularization of the type described by Sydenstricker. We have work in hand to try to interpret some of these difficult and doubtful signs. As Sir Wilson Jameson told you two years ago: "For a beleaguered citadel we are being very well fed indeed," but "the margin of safety we possess must be very small." It has therefore been, and continues to be, important to watch that margin and to seek the earliest signs of malnutrition by carrying out reliable nutritional surveys.

COMMENT ON METHODS

I said that we have been testing all methods, and I might now add a few words about these, although much more work is needed to evaluate them. It is deceptively easy to use a method; it is surprisingly difficult to draw justifiable conclusions. It is worth remembering that a scientist's facts are usually right; his interpretations of those facts are usually wrong.

The sequence of events in the production of deficiency disease points the way to the four groups of methods that are available. Over a period of time a person eats food deficient in a nutrient, and that fact may be detected by dietary methods. Then the concentration of that nutrient may become

diminished in the blood or tissues of the body, and that may be detected by biochemical analyses of blood, tissues, or urine. Later the function of the cells that are most dependent upon the nutrient may become deranged, and that may be detected by certain functional tests such as a measure of the dark-adaptation of the subject, or of the ability to appreciate vibratory sensation. Last, the structure of cells is deranged, and the anatomical changes that result may be detected by clinical methods. Therefore the tools of the dietist, biochemist, physiologist, and clinician are all involved.

I do not wish to go into details of these methods, but I may be allowed to make a few passing comments. Dietary surveys have been valuable in the past for providing evidence about food consumption habits and in assisting the planning of educational programs. But they are laborious, costly, and far more inaccurate than is usually supposed: errors come in at all stages of collection and calculation of the data. Then it is customary to interpret consumption of a nutrient in terms of the supposed human requirements, and our knowledge of these comes at present partly from guess-work and the guesses have not always been very inspired. And there are probably many factors, such as the interrelation between nutrients, that alter requirements and are at present unknown to us. When we have much more accurate knowledge of food composition, of human requirements, and the factors affecting them, dietary surveys may by themselves provide evidence of the extent of malnutrition. They do not at present.

Biochemical methods show great promise, and a number of different estimations can be done upon a small quantity of blood. But the difficulties of most of the methods of analysis are insufficiently appreciated. I have recently seen in the course of a survey

in this country blood drawn and routinely stood at room temperature for upward of 4 hours before the plasma was separated and treated for the estimation of ascorbic acid; great losses might have occurred. Hemoglobin, serum protein, blood (or plasma) ascorbic acid, serum phosphatase and vitamin A are particularly valuable. The first three are routinely included in our mobile surveys, and have been done on blood obtained by a finger-prick in a large survey of children. We have also recently been working on a micro-method for serum phosphatase. But the interpretation of blood analyses is a matter of very great difficulty.

We frequently find low plasma values for ascorbic acid: in the late summer and winter of 1941-1942, 76 per cent of the members of a sample of working class families in Oxford had values below 0.1 mg. per 100 ml. plasma. These values are taken by many biochemists to indicate scurvy, yet I know of no evidence that shows such values are incompatible with full health. In our main survey we have routinely estimated ascorbic acid in the leucocyte-platelet layer of blood since it is probable that this value falls to zero about the time that clinical signs of scurvy begin to develop, whereas a plasma value of zero has not been proved to indicate ill-health.

We perform several other estimations upon blood (such as riboflavin and thiamin), but none of these has yet proved practicable and valuable for rapid public health purposes at the present time. However, the estimation of all water-soluble vitamins in the leucocytes is a technic that may prove extremely valuable for detailed nutritional surveys; certain of them, such as niacin and riboflavin, can be present during clinical deficiency in blood in normal concentration but are low in tissues, and the leucocytes afford a convenient tissue to obtain in surveys. I

know of no analysis of urine that can provide useful information about the state of nutrition in rapid surveys for public health purposes.

Tests of function are disappointing. Dynanometers, spirometers, and the like have had their day, and are now usually relegated to the attic. I still believe in the value of the dark-adaptometer, provided the machine and its operator are reliable and that only poor night-vision that improves significantly upon therapy with vitamin A is taken as a criterion of deficiency of that nutrient; such deficiency is not the commonest cause of poor night-vision in England, but it occurs, and can undoubtedly be diagnosed earlier by this means than by any other.

A clinical examination including biomicroscopy, a medical history, and a dietary history are absolutely essential in any proper nutritional survey. Unfortunately, however, the early clinical signs and symptoms of nutritional deficiency are almost without exception nonspecific; and the slit-lamp microscope is a tool that should only be found in trained and skillful hands, and even then it has not yet revealed any sign that has been proved to be specific. Photography is coming to be used widely in nutritional surveys, and it gives a useful objective record of certain findings; but I emphatically believe that it cannot yet replace an examination by a clinician. X-ray determinations of bone density are promising in the hands of experts; but estimates of capillary fragility, and all anthropometric determinations and indices (except height and weight) are of no proved value. The tools that the medical nutritionist can offer—or should offer—to the public health officer are therefore few. We need more.

TODAY'S DILEMMA IN NUTRITION

The great surgeon and philosopher, Wilfred Trotter, used to call attention

to the lamentable lag between scientific discovery and its application to public health, citing in particular Lind's clear demonstration of the method of preventing scurvy, and its adoption by the Royal Navy after nearly half a century and by the Mercantile Marine after 150 years. That lag still exists, but there is also a lamentable alacrity with which nutritional knowledge or nutritional guesses, derived almost entirely from work on lower animals, are applied to man. Perhaps the reason is obvious. On the one hand, the classical work of Sir Robert McCarrison, Sir John Orr, and others has abundantly demonstrated the tremendous effects of adequate diets and proper nutrition in maintaining sound health; and we know that malnutrition is widespread in many parts of the world although we are extremely ignorant of its precise epidemiology. On the other hand, the science of nutrition has made very rapid progress in the last few years, particularly regarding our knowledge of the nutrition of lower animals. Many have been anxious to apply that animal work to man; and fed by inadequate evidence a fire of uncritical enthusiasm to detect and treat imagined deficiencies has swept our countries, its flames fanned by certain political and vested interests, and when the scientists have left their laboratories they have not always lent a hand at the fire-engine.

Many useless surveys are being made; and many surveys are harmful because unjustified interpretations are put upon the results obtained. There is chaos in this field in both our countries, but it is not coördination that is needed: coördination has been cynically defined as the process of converting disorganized chaos into regimented confusion. We need more scientific knowledge.

THE NEED FOR ADDITIONAL RESEARCH

Since a knowledge of the incidence,

severity, cause, and distribution of malnutrition is so important for public health, we must add to the few methods we already possess of eliciting that knowledge. Such knowledge is even more important in war than in peace, and it will be particularly needed as soon as parts of occupied Europe become liberated, when rapid nutritional surveys should immediately be made to discover the epidemiology of the malnutrition so that proper and adequate relief steps can quickly be taken and secondarily so that observations of nutritional deficiency in man can be made under conditions that should never occur again. Further, the United Nations at Hot Springs were pledged to make food consumption surveys and nutritional surveys after the war. To what source will they turn for advice in that important and integrated task? We have now only a few of the necessary tools, but others are almost within our grasp.

Since our emphasis must be on health in man, rather than on isolated abstractions culled from work on lower animals, we must learn more about the earliest methods of detecting departures from health due to nutritional deficiencies. That can only be done by experiments upon man. Centuries ago work on human nutrition was done by Sanctorio, and by William Stark who twice induced scurvy experimentally in himself and died of it in 1770 at the age of 29.

That work largely failed because the time was not ripe. But such work can and should now be undertaken on an adequate scale. We in Oxford have been studying such induced deficiency in man, using medical students, theological students, conscientious objectors, and ourselves. But no group in this country or in England has fully adequate facilities for properly carrying out such important experimental work.

NUTRITION AND PUBLIC HEALTH

Exactly 200 years ago Lavoisier, the founder of the science of nutrition and a public spirited man, was born. The time has now come to take stock of that science in so far as it affects public health, and it is perhaps the medical nutritionists, rather than the agriculturists or home economists, who should do so. For nutrition is one of the most important fields of public health, and agricultural policy must be guided by the nutritional needs of the people, which in turn are revealed by nutritional surveys controlled by research on human nutrition. And education, for which the home economists have done such excellent work, is an essential part of a national nutrition program and cannot be divorced from the broad field: a nutritional survey itself helps to interest people in what they should eat so that they will obtain their

vitamins from their garden or grocery store, and not from their drugstore.

The public health field of human nutrition, then, is a broad one, and needs full coöperation among physicians, biochemists, home economists, and agriculturists. In England I hope we shall see a division of nutrition in the Ministry of Health working in collaboration with a department of human nutrition in a university, the latter carrying out research and applying it to nutritional surveys throughout the country — and perhaps clinical deficiency states will be included in the notifiable diseases. Then food policy will be guided by sound advice that springs from knowledge, experience, and scientific research directly and critically applied; and rapid advances will be made in what is perhaps the most important field in the domain of human welfare.

Staphylococcus and Streptococcus Carriers*

Sources of Food-borne Outbreaks in War Industry

V. A. GETTING, M.D., DR.P.H., F.A.P.H.A., A. D. RUBENSTEIN, M.D., M.P.H., AND G. E. FOLEY

Commissioner; and District Health Officer, Massachusetts Department of Public Health; and Bacteriologist, Department of Preventive Medicine, Harvard Medical School, Boston, Mass.

WHEREAS enteric infections form the principal type¹ of food-borne disease prevalent in Continental Europe, in the United States staphylococcal food poisoning² is probably the most common of all food-borne diseases. Since this disease is not reportable, we have no accurate knowledge as to the actual number of cases occurring annually. The control of food-borne disease is not only the concern of the epidemiologist³ and of the public health officials, but also of every physician, food handler, and citizen, especially now that we are engaged in total war.

Gastrointestinal diseases are a major cause of absenteeism in industry. McGee and Creger⁴ determined that 18.6 per cent of 40,942 days lost by employees of a Hercules Powder Company plant in New Jersey in 1941 were due to gastrointestinal disturbances. Of 5,402 absences from work, 24 per cent were due to this group of diseases. Of the 7,605 days lost from diseases of the digestive tract, 30.6 per cent were from

gastrointestinal upsets and colon dysfunction, and 4.1 per cent from enteritis and dysentery. Most of the absenteeism from these causes occurred after week-ends and after holidays. We, ourselves, have repeatedly observed food poisoning disrupt a large war plant.

The health officer, the industrial physician, the industrial manager, the food handler, and the consumer himself play important rôles in controlling food-borne disease. Health officers are anticipating an increase in food-borne disease from public eating places and industrial cafeterias as a direct result of the war. More people are eating in restaurants because of the rationing of food and because of the placing of women in industry. There are increasing difficulties encountered in these restaurants. The lack of responsible personnel, trained in the sanitary and proper handling of food, the overburdening of the kitchen facilities, the unavailability of proper equipment, and, in some instances, the short cuts and improper processing of foods are the principal causes for the increase in food-borne disease. Horwood and Pesare⁵ made sanitary surveys of public eating places in Rhode Island and concluded: "Ignorance of accepted

* Presented at a Joint Session of the Epidemiology, Health Officers, Maternal and Child Health, and Laboratory Sections of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 14, 1943.

sanitary requirements and procedures as manifested by the managers and employees of public eating and drinking establishments appeared to be the most important single cause of insanitary practices in such places."

In the investigation of any suspected food-borne outbreak, an analysis of the symptoms will often give the epidemiologist a clue as to the etiological agent. The enterotoxin of *Staphylococcus aureus* produces symptoms in 2 to 6 hours. Whereas fever is a common symptom of food-borne infections it is not a frequent finding in staphylococcus enterotoxin poison. Nausea, vomiting, abdominal cramps or pain and diarrhea leading to prostration are the usual rapid sequence in severe staphylococcal poisoning; chills, sweats, and toxemia are other frequent findings. The onset is more acute than in *Salmonella* infections, the duration is usually a matter of hours and recovery is rapid. In *Salmonella* infections, on the other hand, recovery is a matter of days.

In several instances, green-producing streptococci have been incriminated as the source of food-borne outbreaks. Linden, Turner, and Thom⁶ reported two such outbreaks in both of which cheese was found to be the vehicle. *Streptococcus lactis*⁷ when isolated from this food and fed to kittens produced symptoms similar to those caused by staphylococcus enterotoxin. Carey, Dack, and Meyers⁸ isolated alpha-streptococci from canned sausages in an outbreak involving 75 persons. Living cultures of this organism fed to volunteers produced a syndrome clinically indistinguishable from staphylococcal food poisoning. Bacteria-free filtrates were non-toxic. Similar results were obtained by Carey, Dack, and Davison⁹ in another outbreak caused by this organism. There is, therefore, some evidence that green-producing streptococci may cause gastroenteritis in man. However, un-

like staphylococcal food poisoning, the toxic material is not contained in bacteria-free filtrates of this organism.

The clinical picture presented by this type of food infection resembles that of staphylococcal poisoning very closely. A differentiating feature is the longer incubation period found in outbreaks caused by green-producing streptococci. This usually varies from 5 to 18 hours, with an average of about 12 hours.

DEMONSTRATION OF THE ETIOLOGICAL AGENTS

The application of bacteriological procedures to the study of food poisoning must take account of the diverse etiological agents encountered in these outbreaks. Epidemiological and clinical data may suggest the identity of the causative agent as in botulism but are of less value in differentiating between the more common agents of food poisoning. Assuming the special technics necessary for the isolation and identification of the *Clostridia* to be indicated or excluded clinically, the bacteriologist must provide technics adequate for the isolation and identification of: (1) staphylococci, (2) streptococci, (3) the enteric group. Staphylococci and streptococci were encountered in the outbreaks reported here. Members of the enteric disease group were excluded as possible causes by appropriate clinical and bacteriological examinations.

Nose, throat, and stool cultures were taken on all suspected food handlers. Swabs were cultured on 5 per cent horse blood agar and in beef infusion broth for 24 and 48 hours. Stool specimens were cultured on differential media for members of the enteric disease group.

Adequate epidemiological investigation usually reduces the number of foods suspected in a given outbreak. The foods thought to be responsible were brought to the laboratory im-

mediately or packed in dry ice for shipment.* Representative samples of each food were cultured in beef infusion broth on 5 per cent horse blood agar and differential media for the enteric disease group. Since chromogenesis varies with different media and cultural conditions, the differentiation of all staphylococci was made on the basis of pigment production on beef infusion agar incubated 24 hours at 37.5° C. No detailed study of colony variants was attempted.

The streptococci were classified according to the group-precipitation test described by Lancefield.¹⁰ The serological type of Group A strains was determined by the slide-agglutination technic reported by Griffith.¹¹

Casein hydrolysate filtrates were prepared according to the method of Favorite and Hammon.[†]¹² Filtrates were tested for enterotoxin by feeding to kittens and by the intravenous kitten test described by Hammon.[‡]¹³ Diarrhea and vomiting in 1 to 3 hours following administration of the filtrate was interpreted as a positive reaction.

The results of these toxigenic studies are summarized in Table 1. Unlike *Staphylococcus aureus*, the streptococci studied failed to produce an enterotoxic substance in casein hydrolysate but did produce a toxic substance in sterile tissue media which when administered intravenously to kittens induced an enterotoxic reaction. These substances could be readily distinguished from staphylococcus enterotoxin in that they were non-toxic by mouth. A detailed

study of these tissue media filtrates has been reported by Foley, *et al.*¹⁴ As has been the experience of others,^{8, 15} whole cultures of streptococci produced enterotoxic reactions when fed to kittens.

There are conflicting reports as to the value of the various biochemical technics devised to distinguish enterotoxic strains.^{16, 17} The "potential" enterotoxicity as judged by procedures other than the kitten test does not appear to be sufficient evidence to incriminate either a food or food handler as the source of illness.

Certain biochemical characteristics of the enterotoxic staphylococci isolated from foods and food handlers involved in these outbreaks are summarized in Table 1. Such tests are of some value in establishing the probable identity of strains but do not indicate enterotoxicity. There appears to be a rough correlation between alpha-hemotoxin titer and enterotoxicity as observed by Woolpert and Dack¹⁸ but exceptions were noted.

ANALYSIS OF OUTBREAKS

It is well known that the staphylococcus and the streptococcus are ubiquitous in their distribution. They are found in the nose and throat of healthy persons where they become quite abundant during upper respiratory infections. They are readily isolated from superficial skin lesions and from routine air samples. In spite of modern aseptic surgical technics, they are often incriminated as the cause of post-operative stitch abscesses. It is, therefore not surprising that foods are often contaminated by them.

Our experience with staphylococcal food poisoning has demonstrated that it is by no means infrequent. The few outbreaks coming to the attention of public health authorities represent but a fraction of the actual number. Very often only the most dramatic incidents

* After bacteriological examination, samples were homogenized in a Waring Blender, mixed with milk or fish, and fed to kittens (4-6 months old) which had been starved the previous 24 hours. Typical "enterotoxic" reactions could be produced with contaminated foods by this method.

† In our experience, rotation was not essential to the production of an enterotoxin satisfactory for routine tests.

‡ Results of feeding experiments with original foods and casein hydrolysate filtrates agreed with those of the intravenous test with filtrates of the same strain.

are reported. Sometimes newspaper accounts of such epidemics serve as the first notice to the health officer that something has happened. About half of the outbreaks listed in this paper took place in a single community. The interest of the health officer in this problem was a major factor in bringing most of these to light. We must assume that although rarely reported, similar episodes are a constant occurrence.

Certain of these outbreaks are more apt to become manifest than others. Institutional outbreaks, or those coming after a large gathering where a single meal common to a considerable number of persons has been incriminated, are readily detected. However, in other instances in spite of large numbers of cases, relatively few are reported. Outbreak 10 (Table 1) illustrates this point. The epidemiological investigation revealed that an infected pastry product had been shipped to numerous restaurants and diners in many different communities. For the most part it was sold in individual helpings. Although hundreds of potentially infected pies were distributed, only 60 cases came to our attention. For the most part these consisted of multiple cases occurring among small groups of persons who had eaten together at a single restaurant. In such groups the common source could be established without too much difficulty. "Car sickness" was considered the cause of one patient's illness with symptoms so severe that hospitalization became necessary. A newspaper account of the outbreak eventually led to the association of this case with the epidemic. In individual cases it is often very difficult to pick out any single food as the cause of symptoms. This factor alone tends to obscure the source of many outbreaks and is a definite asset to dirty and poorly managed food dispensing establishments.

The storage of food is an important factor in the morbidity rate. The longer the infected food is kept in a warm place, the greater the attack rates. In each of the outbreaks reviewed here, the epidemiological investigation revealed that the food was kept warm for a period of several hours. Thus certain procedures of food preparation may be the means of incubating pathogenic organisms accidentally introduced.

It has been assumed at times that bacteria harbored in the nose and throat of food handlers may be responsible for staphylococcal and streptococcal food-borne disease. Roberts and Wilson¹⁹ in the study of one outbreak attempted to show that a strain of staphylococcus cultured from infected pastry was the same as that recovered from a food handler. Repeated cultures of this person revealed the same strain for a period of 4 months. Identical organisms were recovered from other food handlers in the bakery.

Our study demonstrates that staphylococcal food poisoning outbreaks may be traced to specific food handlers as sources of infection. In each instance where it was possible to culture the nose and throat of persons responsible for the preparation of an incriminated product, an apparently identical strain of *Staphylococcus aureus* was recovered from at least one of the food handlers and the infected food (Table 1). Although staphylococci are a universal contaminant of the environment, those strains harbored in the nose and throat of the food handler are invariably associated with outbreaks.

Figures collected from several sources¹⁹ showed that the incidence of staphylococcus in the nose and throat of the general population was quite high, ranging from 76.3 per cent to 86.1 per cent in several different samples. Apparently all of these

strains were not chromogenic and only a portion of them were hemolytic.

Utilizing the kitten tests, we compared the incidence of enterotoxin-producing strains of *Staphylococcus aureus* in the nose and throat of food handlers involved in food poisoning outbreaks with that of other food handlers. There was a significant statistical difference between the two groups. Eighteen per cent of a total of 122 in the incriminated group harbored enterotoxin-producing staphylococci, while only 3.4 per cent of the control group of 146 carried such organisms.

Our study suggests that staphylococcal food-borne outbreaks are associated with a high enterotoxin-producing staphylococcus carrier rate among the incriminated food handlers. In four outbreaks, the incriminated strain was recovered from more than one food handler of a particular group. In one outbreak 3 members of the cafeteria personnel in an industrial establishment were found harboring the same organism as that isolated from the incriminated food. Moreover, this appeared to be the identical strain which had been recovered in a previous outbreak 7 months before at this very plant. Another group of food handlers was cultured 5 months after the occurrence of a staphylococcal food poisoning outbreak. Enterotoxin-producing staphylococci were isolated from 3 of the 21 members of this group.

Three of the reported outbreaks were attributed to green-producing streptococci. In two of these, apparently identical strains were recovered both from the incriminated food and the nose and throat of food handlers. Alpha-streptococci of Group H (Lancefield) were involved in one, and of Group B (Lancefield) in two. In each instance, kittens were made ill by whole cultures of the respective streptococcus, but not by its filtrate. The incubation period both in patients and kittens was

prolonged as compared with staphylococcal food poisoning.

Green-producing streptococci belonging to Group H are a common inhabitant of the nose and throat.²⁰ The distribution of this organism should be borne in mind in the diagnosis of obscure food-borne outbreaks where the incubation period is somewhat longer than that of the staphylococcal outbreak and where no other bacterial or toxic agent is demonstrable. Alpha-streptococci of Group B are less frequently encountered²¹ in routine nose and throat cultures. To our knowledge, these three outbreaks are the first reported food-borne epidemics produced by alpha-streptococci classified according to group-precipitation tests (Lancefield).

Outbreak 15 is of unusual interest. A beta-hemolytic streptococcus (Group A, Griffith Type 2) was established as the causative organism. The outbreak consisted of 24 cases of scarlet fever, 56 cases of septic sore throat, 7 cases of diarrhea, 7 cases of nausea and vomiting, and 8 cases of miscellaneous complaints. Gastrointestinal symptoms were unusually prevalent in all the patients. The identical strain of streptococcus was isolated from the throat of the responsible food handler, from the ground ham, and from the throats of several patients. Animal experiments and other laboratory procedures suggest that an enterotoxic substance may have been responsible for the unusually large incidence of nausea, vomiting, and diarrhea. Detailed descriptions of this outbreak and laboratory procedures are contained in other published reports.^{14, 22}

Although three different groups of bacteria were involved in these eighteen food-borne outbreaks, carriers of a specific organism were the apparent source of infection in thirteen. In the five remaining outbreaks, food handling personnel were not cultured.

PREVENTION

One of the most effective methods of reducing food-borne diseases is the enforcement of proper personal hygiene practices by all food handlers. Keeping the hands away from the mouth and nose, covering the mouth with a handkerchief while coughing or sneezing, followed by washing the hands, covering foods whenever possible, refrigerating those that are perishable, reducing the interval between cooking and eating, eliminating food handlers with purulent wounds, boils, or infections of the hand, preventing food handlers with sore throats from preparing food—all these will reduce most of the instances whereby staphylococci and streptococci may contaminate food. One of the methods for controlling the ubiquitous staphylococcus in cream or cream-filled pastries is the rebaking of these delicacies as described by Stritar, Jungewaelter, and Dack.²³

SUMMARY

Food-borne outbreaks in war plants may become an ever increasing cause of absenteeism among workers. Health officers, industrial physicians, and cafeteria managers working coöperatively may accomplish a great deal toward the prevention of food poisoning.

It must be borne in mind that although staphylococci and streptococci are found everywhere in the environment, food handlers carrying such organisms in the nose and throat are almost invariably responsible for food-borne outbreaks. In thirteen out of eighteen outbreaks reviewed in this paper, apparently identical organisms were recovered from incriminated food and the nose and throat of food handlers.

It is suggested that staphylococcal food-borne outbreaks are associated with a high enterotoxin-producing staphylococcus carrier rate among the incriminated food handlers.

Three of the outbreaks were produced by alpha-streptococci, the responsible organism in each instance having been classified according to group precipitation tests (Lancefield). One outbreak had as its etiological agent beta-hemolytic streptococci (Group A—Griffith Type 2).

California Acts on Cheese-borne Typhoid Fever

According to a report recently released by Wilton L. Halverson, M.D., Dr.P.H., Director of Public Health of the State of California, approximately 76 cases of typhoid fever, all of Type C, have occurred in California during the period between April 9 and May 26. Seventy of these cases occurred in four counties, namely, Kern, Tulare, San Benito, and Monterey. Four additional cases have been reported from Nevada.

In view of the fact that all cases were of the same type and since all occurred during the same approximate time interval, it was assumed that the outbreak was from one source rather than from multiple sources.

Epidemiological investigation elicited the information that in various areas cases tended to trade at certain grocery stores. This was especially true in Bakersfield, where practically all of the 20 cases traded at one store.

The investigation elicited the information that the common factor was the ingestion of unripened, unpasteurized cheese of the Romano Dolce type, a type of cheese recently developed in California. When it became evident that well over 90 per cent of all the cases had ingested this type of cheese, a conference was called with representatives of the dairy industry, the University of California, the State Department of Agriculture, and the State Department of Public Health.

According to Dr. Halverson, after the data had been canvassed all concerned agreed that the evidence at hand called for immediate action, namely, the

impounding of all cheese of this type as well as companion types manufactured in the same factories. To this end, action was immediately taken by the State Department of Agriculture, the regulatory agency for dairy products. An intensive investigation of the cheese factories producing cheese distributed in the areas concerned began. Because of complex and overlapping distribution systems, it was not possible to incriminate any single factory.

The previous call for an extraordinary session of the State Legislature for another purpose gave an opportunity to secure legislation to prevent a repetition. The Director of Health requested Governor Earl Warren to request in a supplementary call legislation which would correct this situation. The Governor immediately saw the importance of setting up safeguards to prevent a recurrence and as a result legislation was prepared, has been passed by both houses, and signed by the Governor, which provides that all cheese sold in the State of California must be pasteurized, must be made of pasteurized milk, or must be ripened or cured for a period of not less than 60 days. The bill also provides for proper labeling of the product whether manufactured in or out of the state, and contains an urgency clause which makes it effective immediately.

The short interval of time between the discovery of the cases and the co-operative action on the part of the State Departments of Agriculture and Public Health and the immediate action of the Legislature are notable.

Salmonellosis as a Public Health Problem in Wartime*

A. D. RUBENSTEIN, M.D., M.P.H., ROY F. FEEMSTER, M.D., DR.P.H., AND HELEN M. SMITH

District Health Officer; Director, Division of Communicable Diseases; and Statistician, Massachusetts Department of Public Health, Boston, Mass.

UNDER war conditions, the control of diarrheal diseases, which are a constant threat to the health of our armed forces, industrial workers, and other civilians, is one of the problems demanding increasing attention by health departments. Overcrowding in rapidly expanding industrial centers, an ever-growing shortage of labor and a constantly shifting population, are some of the many factors operating in a wartime environment, which tend to increase the incidence of these infections.

The problem of controlling *Salmonella* infections is at best an exceedingly difficult one. There is complete lack of uniformity among the various states as to administrative practices concerning these diseases. In many areas, where Salmonellosis is not reportable, except for supervision of outbreaks no cognizance is taken of sporadic infections. On the other extreme, restrictions imposed by health authorities are sometimes excessively severe. One state requires that any person excreting paratyphoid organisms, but apparently well, shall be considered a carrier and kept under observation for one year even though repeated stool

cultures are negative.¹ In one Army jurisdiction,² food handlers whose stool cultures are found to be positive on routine examination are hospitalized.

Such lack of unanimity is a direct result of the many unsettled problems concerning the epidemiological and clinical implications of *Salmonella* infections. If it were realized that permanent carriers, except of *Salmonella paratyphi B*, are not frequently discovered as sources of infection, much time would be saved in investigations. Because of the possibility of animal sources for cases occurring in man, human sources have often been ignored. Because some paratyphoid cases are very mild, it has been felt that, except in infants and the aged, these infections are inconsequential and merit no great amount of attention. The complexity of the problem is aggravated by the steadily increasing number of newly discovered *Salmonella* types.

The epidemiological investigations of sporadic *Salmonella* infections are by no means simple procedures. Table 1 lists the 22 types of *Salmonella* organisms recovered in Massachusetts since 1937, together with their possible hosts as recorded in the literature. It is apparent that these organisms have been isolated from many animals and that they are widespread among domestic and wild birds.

* Presented at a Joint Session of the Epidemiology, Health Officers, Maternal and Child Health, and Laboratory Sections of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 14, 1943.

Since outbreaks have been traced to infected meat, there is some likelihood that sporadic cases may arise from a similar source. Salmonella-infected horsemeat has been incriminated in several epidemics reported from Germany.²⁴ It is possible that the increased consumption of horsemeat in this country may present us with an additional source of infection. *S. muenster*²⁵ has been recovered from a

person who developed food poisoning after eating raw horsemeat. Although, in general, meat incriminated in outbreaks has been traced to diseased carcasses, recent investigation¹² has revealed the presence of Salmonella organisms in the meat and organs of apparently healthy animals. Pork and pork products were more frequently infected than other meats.

Eggs belonging to several species of

birds have been occasionally established as sources of infection. Adult ducks and duck eggs¹³ harbor several varieties of *Salmonella* organisms. It has been demonstrated²⁶ that *S. typhimurium* can penetrate the shell of duck eggs. Pigeon and goose eggs used in the preparation of puddings and salads have also been incriminated.^{27, 28} *S. senftenberg* was isolated from a commercial egg preparation during the investigation of an epidemic in Massachusetts caused by *S. paratyphi B*.

Rats and mice may transmit *Salmonella* infection.²⁹ Surveys have demonstrated that wild rats harbor these organisms.³⁰ The house fly³¹ and the mosquito (*Culex pipiens*)³² may serve as additional vectors. Quite recently it was demonstrated that *S. enteritidis* may be transmitted experimentally by the Rocky Mountain wood tick *Dermacentor andersoni*.³³

The multiplicity of sources and vectors is a troublesome factor in tracing sporadic cases. Such investigations are time consuming and, if a large proportion of these infections originate from animal sources, the prospect of successful control is not particularly bright.

PURPOSE AND METHODS

In 1937, during the investigation of several *Salmonella* outbreaks, the frequent occurrence of inapparent infection among those exposed to the causative agent was an interesting observation. In spite of detailed study, the sources of these outbreaks remained unknown. No direct association could be seen with either permanent carriers or animal sources. Subsequently, subclinical infection was often noted among the contacts of sporadic cases. One would scarcely postulate animal sources for *Salmonella* infections of formula-fed infants in immediate contact only with hospital personnel. The primary purpose of this study was,

therefore, to evaluate the rôle of both unrecognized and inapparent infection in the transmission of salmonellosis.

Salmonella infection was declared a notifiable disease. All reported cases were investigated epidemiologically. Wherever possible, stool examinations were performed at suitable intervals in order to determine the total period of infectivity. Contacts were studied for evidence of either clinical or subclinical disease. All positive cultures were typed* and classified according to the Kauffmann-White schema.^{34, 35} Clinical data were collected in order to acquire further information concerning the nature and severity of these diseases.

ANALYSIS OF FINDINGS

A. Epidemics

Table 2 summarizes our experience with *Salmonella* infections in Massachusetts since 1937. As one might ex-

TABLE 2
Salmonella Infections in Massachusetts

Year	Total Epidemic Cases	Total Sporadic Infections	Positive Routine Specimens	Total
1937	228	53	0	281
1938	16	68	3	87
1939	5	31	4	40
1940	73	60	13	146
1941	8	60	9	77
1942	26	90	12	128
1943 *	0	46	6	52
	356	408	47	811

* January to July, 1943

pect, the number of epidemic cases varies considerably from year to year. Sporadic infections remain, on the other hand, at a fairly constant level. The increase noted during 1942 and the first 6 months of 1943 is due per-

* Original isolations were made by the Bacteriological Laboratory of the Massachusetts Department of Public Health, and typing was performed by the Laboratory of the Department of Bacteriology and Serology of the Beth Israel Hospital, New York, N. Y., under the direction of Dr. Erich Seligmann.

haps to a greater interest on the part of physicians in these diseases. It is apparent that a rather extensive reservoir of *Salmonella* infection exists in our population.

Epidemics have been caused by seven varieties of *Salmonella* organisms (Table 3). *S. newington* and *S. senftenberg*, although not often the cause of clinical disease in humans, were each involved in a single small outbreak. Eleven of these incidents were food-borne and, with the exception of one epidemic in a neighboring state (two Massachusetts residents infected with *S. derby*),³⁶ all our food-borne epidemics were due either to *S. typhimurium* or *S. paratyphi B*.

Of the institutional outbreaks, three (one *S. typhimurium*, one *S. newington*, and one *S. cholerae suis*) occurred among the new-born of three hospital nurseries. In one of these, the infection was traced to a mother with a previously unrecognized *Salmonella* infection who shortly after delivery had infected her newly-born infant. The disease then spread to other infants in the hospital nursery. Further investi-

gation in the mother's household revealed that the maid, a second unrecognized case, had initiated this chain of cases which resulted eventually in the death of one infant. There was one fatality in each of the three nursery outbreaks.

Not included in Table 3 is a "sub-clinical epidemic" of seven *S. montevideo* infections which were discovered in an institution where release cultures were being taken following an outbreak of Sonne dysentery. Not one of these persons manifested symptoms compatible with *Salmonella* disease.

B. Sporadic Infections

The investigation of 295 sporadic cases (Table 4) resulted in the discovery of 113 additional infections among the contacts, an increase of 38.3 per cent. Forty-six of these (41 per cent) were clinical cases while 67 (59 per cent) were subclinical. It is significant that the follow-up of 14 *S. paratyphi B* cases, 90 *S. typhimurium* cases, and 23 *S. newport* cases yielded respectively 27, 30, and 10 new infections among the contacts.

Studies among the immediate household contacts of 237 sporadic cases revealed multiple infections in 59, or 24.9 per cent. Two, 3, and 5 infected contacts were discovered respectively in 12, 4, and 6 families.

The relative frequency of the several *Salmonella* types as determined by the occurrence of sporadic cases is given in Table 4. *S. paratyphi B*, *S. typhimurium*, *S. newport*, and *S. oranienburg* are the most prevalent types. All together they represent approximately 70 per cent of all our typed sporadic cases. When arranged according to year of onset, it is observed that the same general pattern of prevalence is maintained each year. Except for *S. montevideo*, which is an occasional finding in routine examinations, these same four types are among those most commonly encountered when routine stool cultures are being taken for one reason or another.

It has been stated in the literature³⁷ that children are more susceptible to

Salmonella infection than adults. When all types are combined, our figures would seem to confirm this opinion. About 29 per cent of all sporadic infections occurred in the first decade of life although each succeeding 10 year period up to age 50 contributed at least 12 per cent or more to the total number of cases. However, when consideration is given to differences in type, we find that in our sample unusual susceptibility in children up to age 10 was shown primarily when *S. typhimurium* was the etiological agent. The percentage of cases under age 10 among the four most frequently encountered types in the sporadic group was as follows: *S. typhimurium* 39.1 per cent, *S. paratyphi B* 24.4 per cent, *S. oranienburg* 20 per cent, and *S. newport* 18.2 per cent. If the *S. typhimurium* cases are excluded from the total sporadic group, the proportion of cases in the age group 0 to 10 drops from about 29 per cent to 23 per cent. Because of the small number of cases,

* Cholecystectomy was performed in one carrier at 30 weeks and one at 40.

no inference could be drawn regarding the more unusual types.

The distribution of the 295 sporadic cases according to the seasons of the year indicates that the highest incidence occurs in the summer and the lowest in the winter. The figures were as follows: spring 66, summer 116, fall 74, and winter 39. The cases were fairly evenly divided between the two sexes: 146 cases among males and 149 among females.

C. Laboratory Studies

1. *Persistence of Infectivity*—Infectivity of Salmonella cases persists for considerable periods of time. Table 5 summarizes the results of serial stool examinations in 710 (87.5 per cent) of our 811 cases. In the 4th week after onset of the disease, approximately 61 per cent of the *S. paratyphi B* cases, and 43 per cent of the *S. typhimurium* cases were still infectious. In the 8th week, the figures for *S. paratyphi B*, *S. typhimurium*, and all other types were 21.6 per cent, 12.9 per cent, and 20.8 per cent respectively. Excluding permanent carriers, 24 cases represent-

ing seven Salmonella types remained infectious for 6 months or longer. Seven of the 24 (1 *S. paratyphi B*, 5 *S. typhimurium*, and 1 *S. give*) continued to harbor the causative organism for at least one year and subsequently became negative.

There are many differences of opinion concerning the significance of positive stool cultures in healthy persons. Whether this condition is indicative of subclinical infection or merely temporary alimentary excretion is of some practical significance. Table 6 presents our findings concerning the persistence of positive stools in 123 cases of inapparent infection. Fifty-four per cent of these cases continued to excrete Salmonella organisms for 4 weeks, 22.8 per cent for 8 weeks, and 10.5 per cent for 12 weeks. The rate of decline in percentage of cases still positive each week approximates closely that noted for all Salmonella infections (Table 5). Seven of our permanent carriers presented no history of any illness suggesting clinical Salmonella disease and are therefore included in Table 6.

Our studies show that age has a decided influence on the duration of positive stools (Table 7). Infants under 6 months of age tend to remain infectious longer than older persons. Twelve (48 per cent) of 25 in this age group had positive stools for 14 weeks or longer. A similar but less marked tendency is noted in infants 6 months to 1 year. In contrast, among older children and

adults the rate of fall is more rapid after the 10th week of illness. Of 46 cases at all ages with positive stool cultures for at least 16 weeks, 14 were under 1 year of age. On the other hand, permanent carriers are for the most part limited to the older age groups.

In 8 of the 14 cases under 1 year of age, the organism was *S. typhimurium*,

the remainder being distributed among five other types. Three infants with *S. typhimurium* infections had positive stools for 1 year or longer, although freedom from infection was finally demonstrated in each instance.

2. *Widal's*—Widal's utilizing *S. paratyphi B* as an antigen were performed in 482 cases, 332 (68.8 per cent) of which manifested some reaction in a serum dilution of at least 1:40 (Table 8). This figure is influenced to a great extent by the large number of positive tests in *S. paratyphi B* cases (172 out of 196, or 87.7 per cent). Of 129 *S. typhimurium* cases, a rise in titer was found in 79 (61 per cent). Information concerning the widal tests was available for 81 subclinical cases; 34, or 41 per cent, were positive. The percentages in the two most common types were as follows: *S. paratyphi B*, 67 per cent (21 out of 31 cases); and *S. typhimurium*, 47 per cent (9 out of 19 cases). In 50 cases representing six Group C Salmonella types, we found an increase in titer in 21, or 42 per cent.

D. Permanent Carriers

During the course of our study, 15 permanent Salmonella carriers were discovered among the 811 cases (Table 9). Their distribution according to Salmonella type was as follows: *S. para-*

typhi B 12, *S. oranienburg* 2, and *S. derby* 1. One *S. paratyphi A* carrier had been recorded several years ago. Twelve permanent carriers (5.1 per cent) developed among 235 *S. paratyphi B* infections; none among 267 *S. typhimurium* infections; and 3 (1.0 per cent) among 309 infections due to all other types. This indicates that permanent carriers are important reservoirs of *S. paratyphi B* infections.

Of these 16 carriers, 9 were convalescent cases which had been followed for 1 year. Seven of the 9 were type *S. paratyphi B*. In 2 instances, because of clinical symptoms referable to the gall bladder, cholecystectomy had been performed before the expiration of the usual observation period. One patient was cured of the carrier condition; the other died shortly after operation. Of the 7 remaining carriers, all of whom had been discovered in the investigation of sporadic cases, 5 were type *S. paratyphi B*. This was a striking finding because there were only 14 sporadic cases of *S. paratyphi B* in contrast to 281 sporadic cases due to other Salmonella types, among whose contacts only 2 carriers were discovered. The source-finding rate for the former was 35 per cent; for the latter, 0.7 per cent. In making this comparison we recognize that in an investigation it is impossible

to demonstrate whether a healthy person discovered to be carrying a Salmonella organism is a permanent carrier or is suffering from a subclinical infection which will eventually develop into the permanent carrier state.

Bile specimens were obtained by duodenal drainage from 6 permanent carriers (4 *S. paratyphi B*, 1 *S. oranienburg*, and 1 *S. derby*). The etiological agent was demonstrated in the gall-bladder contents in each instance. This indicates that in permanent Salmonella carriers, if persistent excretion of the causative organism takes place only in the stools, the gall-bladder is the focus of infection. One *S. typhimurium* case had been followed for 67 weeks before the stools became negative. Examination of the bile 1 year after onset and while the stools were still positive did not reveal the organism. Another case of the same Salmonella type, with positive stools for 48 weeks, is still under observation. The gall-bladder had been removed from this patient many years before, and bile drainage performed quite recently did not demonstrate *S. typhimurium*. However, x-ray studies of

the large bowel revealed diverticula which may account for the continued presence of the organism in the feces.

Three of the 16 carriers were males and 13 females. Except for a boy of 11, all our carriers were 32 years of age or older at time of discovery, the average age having been approximately 46 years. It is, therefore, apparent that some types of Salmonella organisms share with the typhoid bacillus³⁸ a predilection for the gall-bladder of the middle-aged female. Further investigation along these lines will differentiate those types which may in a certain percentage of cases localize permanently in the gall-bladder from others, like *S. typhimurium*, which may be harbored solely in the intestinal tract.

E. Clinical Manifestations

Clinical descriptions were available in 711 cases (Table 10). The principal groups were as follows: gastroenteritis, 425 cases (59.8 per cent); continuous fever, 110 cases (15.4 per cent); and subclinical infection, 162 cases (22.8 per cent).

In our experience, hard and fast dis-

* 4 abscesses (1 *typhimurium*, 3 untyped); 2 meningitis (1 *typhimurium*, 1 *derby*); 1 respiratory (*typhimurium*)

tinctions between Salmonella fever and septicemia were often unjustifiable. In some cases the clinical syndrome, having been initiated as typhoid-like fever, might easily have been regarded during its subsequent course as a septicemia because of septic localization. By the same token one might attempt to differentiate between typhoid fever and typhoid septicemia.

Of the 425 cases of gastroenteritis, 189 (44 per cent) were caused by *S. typhimurium*, and 98 (23 per cent) by *S. paratyphi B*. The remaining 69 typed cases (16 per cent) were distributed among 19 other Salmonella types. A considerable proportion of the *S. paratyphi B* cases (98 out of 143 clinical cases, or 68 per cent) manifested gastrointestinal symptoms. Although in several of these the intestinal symptoms became less prominent later in the course, they constituted, nevertheless, the most striking part of the illness.

Although *S. paratyphi B* cases represented only about 29 per cent of the total number (194 out of 711), this type accounted for 45, or 40.9 per cent, of all the continuous-fever cases. Only 13 *S. typhimurium* infections were included in this category. Continuous fever was the prime clinical manifestation in 6 *S. newport* cases and 7 *S. cholerae suis* cases.

Of 162 subclinical cases, 51 (31 per cent) were *S. paratyphi B*, and 39 (24 per cent) were *S. typhimurium*. A significant number of the *S. oranienburg* and *S. montevideo* cases were subclinical, namely 13 out of 25 of the former, and 12 out of 25 of the latter. Except for *S. cholerae suis*, subclinical cases were frequently noted among all the more commonly occurring types. No evidence of subclinical infection could be found in the examination of the contacts of 5 *S. cholerae suis* cases.

The first reported isolation of *S. tennessee* and *S. urbana*¹⁷ from clinical

cases was made from Massachusetts patients. Previously the former had been recovered only from a healthy temporary carrier, and the latter from fowl and swine.³

In 7 cases the *Salmonella* infection appeared to be incidental, or secondary to some other disease. Three of these "incidental" cases proved to be fatal.

There were 17 other deaths among all our clinical cases, giving a fatality rate of 2.6 per cent. Several of the *S. typhimurium* deaths occurred among the aged inmates of an institution during the course of an outbreak.

Some estimate of the severity of *Salmonella* infections may be derived from the number of cases requiring hospitalization. Out of 295 sporadic cases, 180 (61 per cent) were admitted to hospitals by attending physicians. That severe cases are not limited to any particular age group is indicated by the fact that these hospital admissions were fairly evenly distributed among all ages. Seventy-one *S. typhimurium* cases were hospitalized even though this organism is usually said to produce comparatively mild infections.

COMMENTS

Further study is necessary in order to evaluate more definitely the rôle of animal sources in the human spread of *Salmonella* infections. It must be borne in mind that organisms of the bacillary dysentery group do not require animal hosts for their continued propagation. It is conceivable that the interchange of *Salmonella* organisms between man and other hosts may prove not to be the most significant factor in the epidemiology of salmonellosis.

We have in many instances observed the spread of *Salmonella* infections from case to case. We have seen how the proper recognition of one misdiagnosed case might have prevented eight infections among the contacts in two families. On at least three occa-

sions nurses were infected while caring for *Salmonella* cases. In each instance transmission occurred without the medication of animal hosts.

It is our belief that *Salmonella* infection spreads through the population in small groups of clinical and subclinical cases. Clinical cases may be regarded as indicators of lines of transmission which should be utilized in setting up barriers to check the spread of *Salmonella* infection.

Subclinical infections, unrecognized and unreported cases, are more important than chronic carriers in the epidemiology of *Salmonella* infections. It must be emphasized that temporary carriers are for limited times just as infectious as permanent carriers and are just as capable of producing food-borne outbreaks.

For all of these reasons, we have felt ourselves compelled to keep all reported *Salmonella* cases under observation as long as they remain infectious. By breaking chains of spread in this manner, we believe that many cases have been prevented. In keeping 67 infected food handlers from their occupation, it is possible that some outbreaks may have been averted. At the present time, when the control of diarrheal diseases is of extreme importance, we cannot feel justified in disregarding obvious sources of *Salmonella* infection.

SUMMARY

1. The stress of war conditions demands better control of diarrheal diseases. *Salmonella* organisms are important causes of such diseases.

2. This study is based upon 811 cases of *Salmonella* infection: 356 epidemic, 408 sporadic, and 47 discovered accidentally.

3. The 356 epidemic cases occurred in 17 outbreaks: 11 food-borne, and 6 contact outbreaks.

4. The 408 sporadic infections occurred in 295 households. Four types (*S. typhimurium*, *S. newport*, *S. paratyphi B*, and *S. oranienburg*) accounted for 70 per cent of the sporadic cases

5. Investigation of 295 sporadic cases dis-

closed 113 additional infections among the contacts: 46 clinical cases and 67 subclinical.

6. Of the 711 cases in which clinical records were available, 425 (59.8 per cent) manifested gastroenteritis, 110 (15.4 per cent) continuous fever, and 162 (22.8 per cent) no symptoms (subclinical infections). *S. typhimurium* was the most frequent cause of gastroenteritis and *S. paratyphi B* of continuous fever. These two types were also the cause of 57 per cent of the subclinical infections.

7. All age groups are susceptible to *Salmonella* infection. However, 39 per cent of our sporadic *S. typhimurium* infections occurred in those under 10 years of age.

8. Convalescents are infectious for long periods: 43 per cent showed positive stools in the 4th week after onset, 18 per cent in the 8th week, and 11 per cent in the 10th week. Positive stools persist as long in subclinical infections. Positive stools persist longer in infants under 1 year of age, and longer still in those under 6 months.

9. Sixteen permanent carriers of *Salmonella* organisms have been recorded in Massachusetts: 12 *S. paratyphi B*, 2 *S. oranienburg*, 1 *S. paratyphi A*, and 1 *S. derby*.

10. Twelve permanent carriers (5.1 per cent) developed among 235 *S. paratyphi B* infections; none among 267 *S. typhimurium* infections; and 3 (1.0 per cent) among 309 infections due to all other types. This indicates that permanent carriers are important reservoirs of *S. paratyphi B* infections.

11. In all *Salmonella* types persistent convalescent carriers, subclinical, and unrecognized cases are more important sources of infection than permanent carriers.

12. Although *Salmonella* organisms are common to man, animals, and birds, the interchange between lower animals and man may prove not to be the most significant factor in the spread of salmonellosis.

U. S. Public Health Service Scope Broadened by Legislation

On July 3 President Roosevelt signed a bill aimed to broaden the scope of the U. S. Public Health Service and authorizing federal grants for research by non-government institutions, larger appropriations to aid state public health work, and the establishment of a national tuberculosis program. The bill also provided that public health nurses might be commissioned under the Public Health Service.

The President's statement regarding this legislation was as follows:

The Public Health Service Act is an important step toward the goal of better national health. A constituent of the Federal Security Agency since 1939, the United States Public Health Service is one of the oldest federal agencies—and one in which the people have great confidence because of its excellent record in protecting the health of the nation.

The act signed today gives authority to make grants-in-aid for research to public or private institutions for investigations in any field related to the public health. It authorizes increased appropriations for grants to the states for general public health work.

It strengthens the commissioned corps of the Public Health Service for the enormous tasks of the war and the peace to come. Authority is granted to commission the nurses of the Public Health Service, just as the nurses of the Army and Navy are commissioned.

It provides for the establishment of a national tuberculosis program in the Public Health Service. Since adequate public health facilities must be organized on a nation-wide scale, it is proper that the federal government should exercise responsibility of leadership and assistance to the states.

In establishing a national program of war and post-war prevention, we will be making as sound an investment as any government can make; the dividends are payable in human life and health.

Food Poisoning Caused by Hemolytic Staphylococcus in a Defense Plant*

BENJAMIN J. SLATER, M.D., AND JOHN L. NORRIS, M.D.

Associate Medical Director, Eastman Kodak Company; and Medical Department, Eastman Kodak Company, Rochester, N. Y.

THE nurse was called from the dispensary at Kodak Park at 8:30 p.m. on August 3, 1943, to attend two employees who were violently ill with nausea, vomiting, and diarrhea. Shortly afterward, calls came from various parts of the plant to treat many others. Patients reporting to the main Kodak Park dispensary completely filled every room. It was obvious that we were confronted with a major emergency caused by some gastrointestinal irritant. A hasty survey showed that all cases came from among those people eating the evening meal in one of our numerous cafeterias. Some were in a severe degree of shock with cyanosis and cardiac arrhythmias.

With our own facilities taxed to the limit, it was decided to request aid from the chief Health Officer of the City of Rochester, Dr. Arthur M. Johnson who is also chief of the Emergency Medical Service of the Civilian Defense Organization. He promptly dispatched Dr. Norris Orchard, Deputy Health Officer, to our dispensary while he himself went to the control center of the Emergency Medical Service, according to a predetermined plan for caring for major medical emergencies in this area.

Hospitals were notified that an emergency existed. Beds were made

available, and the emergency wards were staffed in readiness for the arrival of patients while the ambulances were sent from the hospitals.

Dr. Johnson directed the flow of ambulances from the scene to the various hospitals so that there would be no more patients at any one hospital than could be adequately taken care of at one time. It might be mentioned that when this organization was set up, no one thought it would first be needed to serve food poisoning cases on a large scale.

Each ambulance carried one very sick patient and four ambulatory cases. These patients were tagged at our dispensary with name, address, and the medication administered clearly indicated on the tag. In some instances it was necessary to insist firmly that hospitalization was necessary.

Preliminary treatment in our dispensary consisted in evacuation of the stomach as quickly as possible. The finger method was used, together with the drinking of large quantities of tepid water. These methods were effective. By the time the patients had left the dispensary, all their stomachs had been emptied at least once, and in some instances several times. Five patients, desperately ill, received $\frac{1}{4}$ grain of morphine sulfate by hypodermic. As no one knew definitely the cause of the symptoms at that time, it was decided to hospitalize every patient. This

* Presented before the Epidemiology Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 12, 1943.

probably was a good decision. Twenty-four patients were removed to the Strong Memorial Hospital, 15 to the Rochester General Hospital, and 10 to the Genesee Hospital. Treatments varied with the hospital but consisted in the main of forced fluids by mouth when tolerated and glucose and saline by vein. In one hospital magnesium sulfate by mouth, hypertonic salt solution by mouth, and oxygen to those who were cyanosed was used. Doctors and nurses worked long into the night.

Dr. David B. Jewett, senior physician at the Genesee Hospital, furnished a statistical analysis of the symptoms shown by 10 patients. All vomited, 9 had diarrhea, 5 very severely. All but 1 had abdominal pain, and in 3 cases the pain was very severe. Cyanosis was present in 2. Only 1 showed blood in the stool. There was 1 case of auricular fibrillation. The temperature was 100° or above in 7 cases, the highest being 103.2°. There was a leucocytosis of over 10,000 in 6 cases; the highest count was 31,000. In 4 cases there were albumin and casts in the urine. Cases at the Strong Memorial and Rochester General Hospitals showed in general the same signs, symptoms, and laboratory findings.

Dr. Charles M. Carpenter, for the Health Bureau, isolated hemolyzing staphylococcus in the vomitus in nearly all cases admitted to the Strong Memorial Hospital, and in some instances the same organism was isolated from the stool.

One patient later developed an acute appendix which was removed. Another developed suggestive symptoms but was not operated upon. One patient developed a low-grade pneumonia 6 days after his return from the hospital. This promptly responded to sulfathiazole therapy. There were no deaths. All cases, with the exception of the appendix case, returned to work after

4 weeks. Sixty per cent returned after the first week.

Eighty-one employees in all were affected. Thirty-two individuals who went home before being taken ill, or who went home rather than report to the dispensary, were treated either by home remedies or by the family physician. Their period of absence closely approximated those who were hospitalized. Symptoms in nearly all cases began from 2½ to 3 hours after a meal was ingested at the one dining room previously mentioned. The acute symptoms in most cases persisted through the night. For two or three weeks many patients complained of various aches and pains, abdominal cramps, and some degree of prostration. Most patients returned to work within 17 days.

One of our first interests, of course, was to determine the cause of this epidemic. It was soon evident that all the people affected had eaten their evening meal in one cafeteria, and they all had eaten corned beef.

The cafeteria system at Kodak Park consists of a main kitchen where food is prepared and distributed to various dining rooms about the plant. On the morning of August 3, 1,000 pounds of fresh corned beef was cooked and sliced with a mechanical slicer. It was distributed to five dining rooms. A portion was served at the noon and evening meals. After the noon meal, normal practice has been to take the unused portion of the food back to the main kitchen where it is refrigerated and prepared for the next meal. In an effort, however, to save gasoline, this practice was abandoned two months previously, and the plan called for refrigeration after the noon meal in the local cafeteria. This necessitated, in some instances, overloading of the refrigerators, as they were not planned to take care of this additional load.

There were no cases following the

noon meal. One patient ate corned beef at the same dining room both at noon and in the evening. This patient had no difficulties following the noon meal.

Closely following the episode, all food handlers were carefully examined by our Medical Department. One employee in the kitchen who handled the meat, presumably with a knife and fork, showed an infected, untreated laceration on the third finger of the left hand, culture of which, taken by the Health Department, showed a hemolyzing staphylococcus. From another employee with facial acne the same organism was isolated by the Health Department. This employee did not assist in the organizing or preparation of the food. It is assumed that the epidemic came about by the contamination of the corned beef by the infected finger. Quite possibly, although it was not proved, this meat was not refrigerated sufficiently in the ice box.

We are convinced that a daily inspection of the hands, arms, and fore-

arms of the food handlers is necessary, and they should be asked at this time if they have any boils, pimples, or infections of any kind on any other part of the body. Ample refrigeration space should be provided for the proper refrigeration of foods, for it is known that bacterial growth proceeds very rapidly at room temperatures, and that standing for 5 or 6 hours is sufficient time for gross infection to take place. There should be some one person responsible for the carrying out of these precautions. Only eternal vigilance will keep a similar catastrophe from any large eating establishment.

We were acutely aware of the value of an organized Emergency Medical Service to the community. In any sizeable community it is possible for large numbers of people to be taken ill in this way or to be injured at one time, and an organization of this sort eliminates most of the confusion which is inevitable when large numbers of people require hospitalization within a short period of time.

Housing the Health Department— An Experiment in Rural Oklahoma

GERTRUDE NIELSEN, M.D., AND HENRY L.
KAMPHOEFNER

*Director, Cleveland County Health Department, Norman, Okla.; and Professor
of Architecture at the University of Oklahoma, Norman, Okla.*

CLEVELAND COUNTY is located in the central part of the State of Oklahoma. It is adjacent to Oklahoma County where the capital, Oklahoma City, and the State Health Department are located. It has an area of 555 square miles. It has no industry and most of the land is not specially suitable for farming. There are one city and three townships, each having a high school as well as grade schools. The 57 one-room schools are spaced at the traditional 3 mile distance from each other. The county government is in the hands of three county commissioners. Norman, the county seat, has the city manager form of government. At Norman are located the State University with a normal enrollment of about 6,000 students and the Central State Hospital housing about 3,000 mentally ill patients.

The population of the county has increased from 27,728 in 1940 to 31,028 in 1943. In 1942 the stable character of this small town, rural and university community, was altered profoundly. The establishment of four naval projects attracted thousands of construction workers. After the completion of the bases about 20,000 sailors and their followers moved in. Crop failure compelled many farmers to leave the county to seek employment in industry. Thus, the population of the rural areas became depleted, while the urban centers became congested.

Several federal and local housing projects are under construction to relieve this situation.

The Cleveland County Health Department was established as a four-member unit in the fall of 1936. During the first two years its housing facilities were inadequate. It was located in discarded storerooms on the second floor of Main Street stores or auto repair shops. Its waiting room was the WPA sewing room, and visitors had to wade through bundles of old clothes to get into the one room which served as interview, examination, and treatment room. In one corner the director and the clerk shared the same desk. A notable improvement occurred in 1939 when the county commissioners rented a neat 5 room residence. In 1940 a new courthouse was erected and from the salvaged material of the old structure an annex was built to house the welfare departments, the food stamp office, and the health department. A community hall was included in the building. The whole department consisted of 5 rooms on the south which were not planned with any particular function in mind. A long hall served as a waiting room for patients as well as for clients of the welfare departments. In 1941 considerable equipment was added and the quarters were improved by venetian blinds and asphalt tile floors. By 1943 the staff had increased to a director, 2 sani-

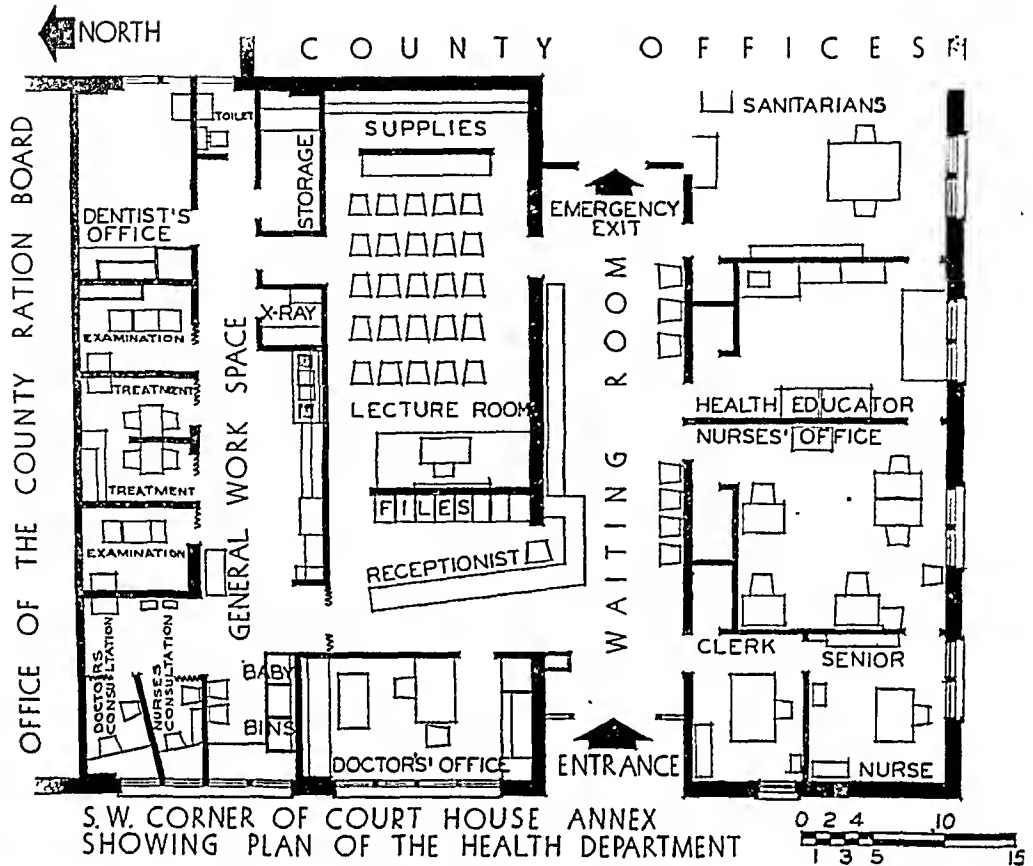

FIGURE 1—Floor plan. South of waiting room original quarters. North of waiting room newly converted space.

tarians, 5 nurses, 2 clerks, a follow-up worker, and a manual helper. The budget had grown from \$9,000 in 1936 to \$24,760 in 1943, that is, from 36 cents to 79.8 cents per capita. Obviously the housing facilities were quite inadequate to take care of the work load.

In January, 1943, an application for additional space was made to the FWA. In March, 1943, the sum of \$10,000 was granted by presidential order, and the conversion of half of the community hall was approved by the FWA and the county commissioners. On July 1 the contract was let. The work started 2 weeks later and was completed in 10 weeks.

In making the plans the function of each new unit was first considered and then the whole was tied together so as

to insure compactness and functional efficiency. The original 5 rooms were readily remodeled into offices for the clerk, the senior nurse, the nurses, the health educator, and the sanitarians. The original waiting room was retained as such, but by making a new outside entrance and changing the original entrance to an emergency exit, the whole department was separated from the rest of the building. This conversion was easily done with very little expense.

The space north of the waiting room had an area of 32 by 60 feet; the ceiling was 14 feet high and the windows were high and narrow. In the conversion the ceiling was lowered to 9 feet and the windows were lowered and broadened. The bare cement floor was covered with asphalt tile.

Somewhat over \$7,000 was spent on

FIGURE 2—Waiting room with clerk's desk.

general construction in converting the old community hall into the various spaces and services as shown on the floor plan (Figure 1). Figure 2 shows the shape and simplicity of the general waiting room and clerk's desk. At the recommendation of the War Production Board, sani-finish tile walls were used to cut down on carpentry labor which at that time was critical in this area. All moldings, fixtures, extras, etc., were eliminated. Most of the lighting was from concealed sources, avoiding the use of expensive metal fixtures and giving better illumination. Many substitutes were worked into the scheme in line with the government's policy of conservation of critical materials.

Because of the definite limitation on exterior light or window space the function of the plan was carefully studied, and the services that could most easily be carried on without direct outside light were placed along

the north wall, which was common to the Health Department and the County Ration Board. The clerk or receptionist was placed at a pivotal position to control the entire space, and the doctor's office was made easily accessible to all. All of the filing space was consolidated behind the receptionist's counter so as to be convenient for the clerk and easily accessible to the doctor and the nurses. Figure 3 shows the general work space with sink, refrigerator, and immunization table, with sterilizers on the right. Behind the curtained openings are two examination rooms and a treatment room. This room is divided into three spaces by a tile partition. With one set-up on the table the doctor can treat two patients alternately, with complete privacy for the patient.

The doctor's and nurse's consultation rooms were worked out with an oblique partition to handle the special

FIGURE 3—General work space. Behind curtained openings are two examination and two treatment rooms.

functions of their space. Figure 4 shows the arrangement of the latter room, and the bins for the undressing

of the babies. Three babies can be handled at the same time under good natural and artificial light. A simple

FIGURE 4—Dressing room for infants and nurse's consultation room.

FIGURE 5—Director's office.

light trough above serves as shelf space for demonstration materials for the infant clinic. A shelf for scales and other equipment is conveniently located and ample room is provided for the mothers, out of the general circulation. Scales for the school children are placed against the wall facing the doctor's and the nurse's consultation rooms.

The doctor's office, shown in Figure 5, is a simple and workable arrangement of the requirements of the space. Figure 6 shows the class and demonstration rooms. The rear wall has an opening for a projector which is operated from the supply room. Blackboard, bulletin boards, speaker's rostrum and a lantern screen are an integral part of the room. This room is already a popular and valuable asset to the health department. On one afternoon a week a maternity class is held here. On infant and preschool and

general clinic days demonstrations and films are shown. This room also serves as a meeting place for various health committees.

FIGURE 6—Class and demonstration room.

All of the space has been carefully studied for its particular use, with thought of simplification, ease of circulation, and efficiency. The cabinets have been worked out after a study of the use they would have. In the storage room there are a hot water tank and especially designed shelves for posters, school bags, incubators, etc. The supply room is lined with shelves and is for the storage of literature, and it consolidates this important part of the health program in an accessible and well organized space.

The arrangement can be easily adapted to special activities. On x-ray

clinic days screens for individual dressing rooms for men can be set up in the lecture room and the examination rooms used for women.

In the preliminary development of the working arrangement, a study was made of published health department layouts, with considerable attention given to the comprehensive analysis of health department requirements made by Marshall Shaffer and August Hoenack of the U. S. Public Health Service in Washington, D. C.*

Thirtieth Anniversary, New York City Bureau of Health Education

Commissioner Ernest L. Stebbins of the New York City Department of Health announced on July 1 that the Bureau of Health Education of the New York City Health Department had completed 30 years of activity. New York City was a pioneer in developing health education programs, the beginnings of which grew out of the tuberculosis campaign initiated in New York City in the early 90's and which demonstrated the superiority of educational measures over the former practice of mere police enforcement.

Since 1914 the Bureau has steadily expanded its facilities until today it makes use of every recognized pub-

licity medium to teach good health to the residents of the city. During the past year each month there have been supplied to the public between 200,000 and 300,000 booklets and pamphlets on the widest variety of health topics and about 250 motion picture showings a month have been arranged. Extensive use of the radio has been made with frequent spot announcements, and neighborhoods are being organized as communities for educational projects against tuberculosis, diphtheria, syphilis, gonorrhea, and other communicable diseases as well as on behalf of a nutrition program. Savel Zimand is Director of the Bureau of Health Education.

An Automatically Controlled Suction Device for Field Air Sampling*

A. SETTERLIND, M.S., F.A.P.H.A.

Chief Chemist, Division of Industrial Hygiene, State Department of Public Health, Chicago, Ill.

IN practically all industrial hygiene studies and investigations, air sampling of contaminants is a necessary part of the procedure. For a few of these contaminants, special devices have been designed and constructed with which it is possible to determine their concentration directly in the field. For others a measured quantity of air may be obtained by the use of evacuated flasks, aspirating bottles or gas pipettes.

For the great majority, however, the technic consists of passing air at a suitable rate of flow through one or more absorption bottles, tubes, or similar devices capable of trapping the contaminant. After this is done the sample is brought in to the laboratory for analysis.

The volume of air to be thus sampled depends upon the sensitivity of the chemical method and the accuracy desired. Usually, the larger the sample taken, the more accuracy is possible in the chemical determination.

In regard to the chemical determination, we have the advantage of a variety of methods, the accuracy and sensitivity of which are usually well known and controlled. But it is well to remember that just because the chemical determination of the contaminant is accurate, it does not neces-

sarily follow that the final result, that of the concentration of the contaminant in air, is equally accurate. This is due to the fact that the overall accuracy also depends upon the accuracy with which the air volume has been measured.

The measuring of the air volume, under field conditions, presents numerous difficulties which often result in errors far exceeding those associated with the chemical procedures. Furthermore, these errors are largely unpredictable because they are introduced as a result of various limitations in the measuring devices or conditions associated with the device used in aspirating the air.

The most common means used today for producing the necessary air flow through an absorber is some sort of a suction pump usually driven by an electric motor, but sometimes manually operated. The device used for measuring the air flow is either a vacuum gauge or, more often, the conventional Venturi type flow meter. While these instruments are capable of registering the air flow with good accuracy under controlled conditions, such as may be obtained in the laboratory, field conditions are often such that highly accurate information of the air volume sampled is difficult to obtain. This is due to the fact that these devices are not integrating the air flow over the entire period of sampling, but are only indicating the rate of the air flow at any given moment. Consequently if an ac-

* Presented before the Industrial Hygiene Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 14, 1943.

curate estimate of the air volume is to be obtained it is imperative that the air flow remain constant. It is this requirement which is the most difficult to achieve, and the failure to maintain uniformity is, I believe, responsible for most of the errors associated with air flow.

When using motor operated pumps repeated line voltage variations cause corresponding variations in the motor speed and consequent changes in the rate of air flow. These variations become especially serious at low rates of flow if it is obtained by controlling the motor speed with a rheostat and thus causing the motor to run below rated voltage. Particularly is this true with respect to small fractional H.P. motors of the universal type which are desirable to use for reasons of versatility. Some improvement may be had by using a constant voltage controlled motor in combination with a bleeder valve in the suction line. However, our experience has been that this will not satisfactorily control the air flow, especially at low rates of flow. That is because constant voltage does not necessarily result in constant speed, it being achieved only when the electrical and frictional resistances have become constant.

Other disadvantages associated with the liquid flow meters mentioned are:

1. Accidental loss of liquid in transportation
2. Loss of liquid due to surges produced by stepping on the suction hose or accidental breaking of its connections
3. Condensation of water in extremely cold weather, causing water to enter the u-tube or condense on the orifice
4. Difficulties in changing orifices when widely different ranges of air flow are desired

Consequently, if highest accuracy is to be obtained it requires two persons to obtain a sample; one to operate the suction device and one to pay attention to the collection of the sample.

In order to overcome the above difficulties, all of which are detrimental to an efficient and accurate sampling technique, our office undertook to develop an improved type of instrument which in its final form proved to be satisfactory.

In planning this instrument, certain minimum specifications were set up which it had to meet to be considered successful.

1. Air flow should be automatically, or at least semi-automatically, controlled.
2. It should be simple in construction and at the same time rugged, and easy to operate.
3. It should be applicable to both low and high sampling rates with equal accuracy; that is, in the range from 0.5 liter per minute to 28.3 liters (1 cu. ft.) per minute.
4. Parts should be easily accessible in the case for cleaning and repair.
5. It should be light in weight for maximum portability.

Theoretically the problem looked relatively easy. Several schemes were tried with regard to controlling the air flow automatically, and instruments were built and tested. While they met the specifications with regard to flow control, they did not satisfy the above specifications in one or more respects. Not until an entirely new type of flow meter had been devised, was a satisfactory solution achieved.

Inasmuch as this flow meter is very easy to construct and has proved exceedingly accurate and useful in connection with hand operated suction devices, it will be described in detail.

Basically the flow meter consists of a vertical cylinder in which a piston is allowed to move freely. The piston is provided with an orifice the size of which depends upon the rate of flow desired. When suction is applied above the piston, air will flow through the orifice. At a certain vacuum the pressure on the underside of the piston will be great enough to lift it and make it travel up in the cylinder. When the piston is floating steadily at any one

point, the air passes through the orifice at exactly the desired rate. A slight excess in the rate will make the piston rise, a slight reduction will make it fall.

In practice it is rarely possible to operate a suction device so uniformly that the piston will remain stationary for any length of time nor is that desired. It should be operated in such a manner that the piston is slowly rising and falling. *It is to be noted that the volume of air passing through the orifice in excess of the rated volume while the piston is rising a certain distance is exactly equal to the amount of reduction in air volume passing through while the piston is falling the same distance.*

Thus the average rate of flow will be exactly equal to that obtained if the piston were kept stationary.

Construction of the flow meter—A flow meter of the type shown in Figure 1 may be constructed from a 50 ml. hypodermic syringe. One discarded due to a broken tip will do as well as a new one.

FIGURE 1

The plunger should move easily in the barrel. Test it, after first inserting a rubber ring in the bottom of the barrel for protection, by holding it in a vertical position and letting the plunger drop of its own weight. It should travel smoothly and evenly to the bottom. Repeat the test a number of times, each time turning the plunger a fraction of a turn. If in any position the plunger should jam or slow up, indicating a tight fit, the barrel and plunger should be reground until satisfactory performance is obtained. This is easily done by making a thin slurry of fine carborundum powder in water, drawing a small amount of it into the syringe and working the piston back and forth with a rotary motion, turning the plunger now and then a fraction of a turn.

After having obtained the desired fit, have a glass blower replace the fine bore tip of the syringe with a 1" piece of glass tubing, 6 mm. inside diameter, to serve as air inlet. Cut off the plunger 1½" from the lower end and grind the edge flat. This piece will serve as the piston of the flow meter. Drill a ⅜" hole in the center of the bottom of the piston to take a standard 5/16" brass connection as indicated in the drawing. The brass connection is provided with an orifice plate made of sheet brass or lead and screwed tight by means of a cap against the seat which is covered with a gasket. The cap should be center-drilled with a 3/16" drill. The size of the orifice is determined by the trial and error method.

It is of course possible to cement a suitable size orifice directly over the bottom hole of the piston and obtain desirable results. However, the use of the brass connection not only provides a simple means of exchanging orifices but also provides added weight to the piston. A heavy piston will be relatively less influenced by frictional resistance in its up and down move-

TABLE 1

Calibration Data

Test No.	Liters Passed	Time in Seconds	Rate of Flow lit./min.	Deviation from Average Per cent
1	7.1	903	0.472	-0.21
2	7.1	901	0.473	±0.00
3	7.1	902	0.472	-0.21
4	7.1	899	0.474	+0.21
5	7.1	899	0.474	+0.21
6	7.1	901	0.473	±0.00

Average rate of flow = 0.473 lit./min.
 Max. deviation from average = 0.21%

ments. A total weight of 45 to 50 gm. has proved to be the most satisfactory.

A piston may also be made from brass, as has been done in the instrument later to be described.

A flow meter constructed according to the above description was provided with an orifice to give a rate of flow of approximately 0.5 liters per minute. In calibration tests it was connected to an absorber and air drawn through by means of a midget impinger pump (which had been slightly altered to serve the purpose) and operated in prescribed manner. The air volume was measured by means of a wet meter.

As shown in Table 1 calibrations gave an average rate of flow of 0.473 liters per minute with a maximum deviation from the average of 0.21 per cent.

Automatically controlled air flow—

The idea suggested itself that this device could be modified to control the air flow automatically. The simplest possible means for accomplishing this would be to let the piston itself cut off the air stream when the desired rate of flow is exceeded. Such an arrangement is shown in Figure 2. It is similar in principle to that used in the M.S.A. midget impinger.

In practice, this device would be operated so that the rubber pad attached on top of the piston would press against the air outlet.

Two different locations of this flow

meter are possible; (1) in front of the absorbers, and (2) at the outlet of the suction device. In the former case, suction is applied to the outlet of the flow meter; in the second case, pressure is exerted at the inlet.

Table 2 shows calibration data for both locations under various conditions. The air flow was produced by means of a motor driven rotary pump. Inasmuch as it was desired to obtain figures which would reflect the maximum variations which it might be possible to obtain in the field by various operators, the suction pump was operated at arbitrarily chosen speeds without any attempts to obtain any check results. Study of Table 2 shows that while this control device after proper refinement might possibly be used if connected in front of the absorber, it is unsuitable if used on the outlet side of the pump.

For practical reasons, however, it is highly desirable to use the flow meter on the outlet side of the pump. Con-

2	High speed	0.774	+44.7

sequently, some other means of controlling the air flow had to be found.

As shown in Table 1 the most accurate air flow is obtained when the plunger is slowly rising and falling. It was felt that this mode of action should be maintained and be utilized for controlling the air flow.

The use of a photoelectric device, where the piston would interrupt a beam of light when rising to a certain point, was considered as a possibility for controlling the motor driving the pump. However, this was considered too delicate and complicated to incorporate in a field instrument and was abandoned in favor of a directly actuated switch. In order to obtain maximum reliability such a switch should fulfil the following requirements:

1. Have the capacity to carry the total operating current.
2. Produce instantaneous response when actuated.
3. Require minimum power for its operation; that is, not materially resist the movement of the piston.

4. Electrical contacts should resist corrosion and pitting.

After a number of different types of switches had been designed and tried, the design shown in Figure 3 finally proved satisfactory.

Essentially it consists of a metal ring of slightly smaller diameter than the cylinder, and free to move up and down a small distance. Normally this ring is resting on the two halves of a split metal ring permanently fastened to the lower end of a cylindrical plug made from plastics. The diameter of this split ring is slightly less than the inside diameter of the piston. Each half of the split ring is electrically connected to the opposite terminals of a fixed resistance which in turn is connected in series with the motor. The piston when traveling upward will eventually lift the ring, thus opening the short circuit which in turn slows down the motor, causing reduction in air flow. As a consequence, the piston will travel down until the metal ring again makes contact with the split ring and thus short circuits the re-

sistance and speed up the motor. To insure good electrical contact, the ring contact is wound with platinum wire and the contact surface of the split ring halves covered with platinum foil. A suitable condenser is connected across the terminals of the latter to minimize arcing.

The plug may be turned from any convenient plastics. It should be provided with means of holding it securely in place in the top of the cylinder. A hole $\frac{3}{8}$ " in diameter bored through the center serves as an outlet for the air.

Inasmuch as very small fluctuations are accomplished by the plunger when in operation, it is best to provide a tripod on which the plunger rests when not operating. This may be easily constructed by soldering three stiff wires to the inside wall of a 1" long brass tubing of slightly smaller diameter than the inside diameter of the barrel. The points on which the plunger rests should allow a clearance between the plunger and the ring contact of from $\frac{1}{4}$ " to $\frac{1}{2}$ ".

FIGURE 4

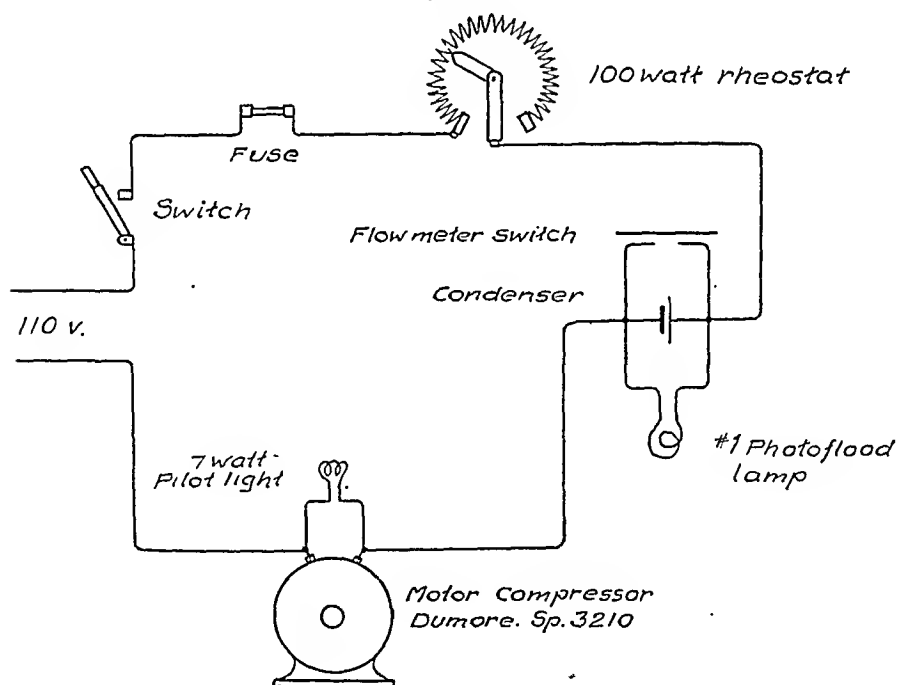

Figure 4 shows the wiring diagram of the assembly. For good operation the fixed resistance mentioned above should be so selected that approximately 10 volts variation occurs across the motor between the open and closed position of the switch at full load. With the type of motor compressor shown, this is achieved with a No. 1 Photoflood lamp. Incidentally this lamp may be used as a visual indicator of how the device is working. In the model shown, a pilot light visible through the panel also serves the same purpose. This light is connected across the terminals of the motor. It enables the operator to see at a glance even from a considerable distance whether the collection device is working properly or needs adjustment. A fast flicker of the light indicates proper operation. If the light is steady the speed is either too slow or too fast.

No lubricant is used or needed. As a matter of fact, if lubricant is applied the piston will stick, which prevents the device from functioning. For this reason a trap, preferably filled with copper wool, should be connected in the line between the pump and the flow meter to prevent the accidental entry of oil into the cylinder.

Hinged panels on the case are provided to permit easy access for inspection, cleaning, and repair.

A trap is located on the inlet side of the pump identical in construction to that on the outlet side. These traps not only serve as protection for the pump and the flow meter but also act as mufflers against the otherwise noisy operation of this type of pump.

Table 3 shows calibration data obtained with this instrument. An effort was made to simulate the various ways the instrument might be operated by different operators. Thus the maximum deviation of 0.95 per cent shown in the table should represent the highest error to be expected at any time. While this in itself is an extremely good performance, even better results may be obtained if each individual operator calibrates the air flow, running the instrument in the same manner as he would do it in the field. Personally, being familiar with the instrument, I have no difficulty in obtaining any number of calibrations showing less than 0.5 per cent variations.

Theoretically there should be no difference in the rate of flow when absorbers of different resistances are used on the suction side. In the previously shown calibrations one absorber was used in the tests because with this type of absorber we have as yet

TABLE 3
Calibration Data of Automatically Controlled Suction Device
(one absorber used)

Test Run No.	Manner of Operation	Volume of Air Passed Through Flow Meter	Time of Run	Rate of Flow lit./min.	Deviation from Average in Per cent
1	Lowest practical speed—Lamp resistance barely glowing	56.8 lit.	27'03"	2.10	-0.95
2	Low speed — Lamp resistance glowing faintly	"	26'58"	2.11	-0.47
3	Higher speed—Lamp resistance glowing strongly	"	26'44"	2.12	±0.00
4	Highest practical speed—Lamp resistance glowing very strongly	"	26'27"	2.14	+0.95
5	Motor started cold the following day — Operated like Sample No. 2	"	26'45"	2.12	±0.00

Average rate of flow = 2.12 lit./min.

Maximum deviation from average = ±0.95%

found no need for greater numbers when sampling. However, recognizing the possibility that such occasion might occur the experiment recorded in Table 4 was performed. Notice the high vacuum required for these absorbers at this rate of flow. The drop in rate of flow becomes progressively higher with each additional absorber.

TABLE 4

Comparison Between Rates of Flow When Using Different Numbers of Absorbers in Series

<i>Number of Absorbers Used</i>	<i>Suction Required Inches of Mercury</i>	<i>Rate of Flow lit./min.</i>	<i>Variation of Flow in Per cent</i>
1	2.5	2.12	± 0.0
2	5.0	2.08	-1.9
		2.08	
		1.97	
3	7.5	1.99	-6.6
		1.98	

While this performance was not noticed when the instrument was new but showed up in this test after about 150 hours of operation, it must be taken into consideration if the pump has to work against very high resistance. It is caused by air leaking in through the bearings of the rotary pump. Consequently it is advisable, as is the case with all these devices, to make periodic

calibrations, and especially when unusually high vacuum is to be used for inducing the air flow.

The instrument just described and demonstrated has proved itself exceptionally trouble-free. This is probably due to two factors: the presence of the protective traps on each side of the pump and the reliability of the switch. The latter is, of course, the source from which most of the trouble would be expected. However, since the instrument was built and passed through the experimental stages, it has been in use approximately 150 hours, during which time the switch has opened and closed without a single failure for an estimated million and one-half times, a record which seems rather satisfactory.

While the instrument as described was designed to meet our own demands for portability and refinements, I see no reason why the control device could not be successfully adapted to some of the already existing suction devices. I suggest that you try it. If you succeed I shall feel happy to have contributed, in whatever small degree it may be, to the achievement of that other freedom we also so ardently desire, namely, freedom from trouble.

CLIFFORD CAUDY YOUNG

THE death (on June 5) of "Cy" Young was a blow to the cause of public health in the United States and a saddening loss to the hosts of his friends and colleagues.

Born in 1887, Young took his A.B. and M.S. at Kansas, studied for a time with Sedgwick at M.I.T., and received the degrees of Dr.P.H. (1924) and D.Sc. (Hon., 1942) at Michigan. He served for two years as an officer (S.C.) in the First World War, and was appointed Director of the Bureau of Laboratories of the Michigan State Board of Health in 1919—a position which he held until his death. He married Minna Crooks, one of his associates in the laboratory in 1925. He headed the Department of Preventive Medicine and Public Health of the Wayne University College of Medicine from 1931 to 1938. He was a Charter Fellow of the A.P.H.A.; and served as Chairman of the Committee on Meetings and Publications (1932–1936) and member of the Executive Board (1941–1944).

The Laboratory of the Michigan State Health Department was Dr. Young's life work and will always remain his monument. Beginning with thirty-six thousand diagnostic tests, he built this branch of service up to over one million tests a year. He developed a state-wide system for the supply of completely free biologic products; and among the many fruits of this system was one of the most sweeping reductions in an initially high diphtheria death rate ever accomplished in the United States. He was a pioneer in the control of goiter by iodization of water supplies; and one of his last major accomplishments was an admirable program for supplying free blood plasma to every citizen in need of that almost magic remedy. Paul de Kruif has stated that this state laboratory was "one of the most functionally beautiful and powerful life-saving institutions in human history."

We have used the words "served" and "service" three times in this brief editorial; and it is an idea which is inevitable in connection with "Cy" Young. His complete technical skill and great administrative ability was infused with an almost passionate zeal for bringing the fullest resources of medical science to

every man, woman, and child in Michigan. De Kruif has said that, in the death of Dr. Young, "our state has lost the most valuable of all its citizens."

To all public health workers, the career of Dr. Young should be a reminder of the real significance of what we are doing, and trying to do. Steadily and undramatically—often without public recognition—the health officers, the engineers, the doctors, the nurses, the laboratory workers, and the rest are rendering a service which represents one of the most precious of all contributions ever made to the welfare of the human race.

THE NEW WORLD ORDER

THE aims of the American Public Health Association are primarily technological and relate to the clarification of objectives and the improvement of procedures in the field of public health practice. Public health is, however, one of the most far-reaching of human endeavors. It cannot be limited by national boundaries, since the disease germ operates under all flags. The recently discovered new type of epidemic jaundice is a problem in Berlin and in Moscow, as well as in Cairo. Nor can the specific challenges of public health be separated from the wider problems of national and international economics. The first step in the control of tuberculosis and infant mortality—in France, in Poland, in China—must be the provision of food for starving populations and the restoration of those populations to a status of economic independence.

The health officer, with his colleagues in the various specialties of public health, has a vital interest in the development for the post-war period of a world health organization of some sort. Whether it should be based on a reactivation of the Health Section of the League of Nations (which is still in being), or the health services now being developed by UNRRA, or on some new organization yet to be created, is a problem for the future. It is certain, however, that we need international machinery to maintain a world-wide system of epidemiological intelligence; to provide consulting field service and grants-in-aid to nations needing help in dealing with special problems; to negotiate sanitary conventions; to establish international technical commissions for the coördination of the best available knowledge in regard to malaria, venereal disease, tuberculosis, maternal and child health, housing, nutrition, medical care, and the like; and to coördinate facilities for the training and distribution of personnel. An outline of possible approaches to the "International Organization for Health" has been prepared and is available for study and criticism.¹

The public health worker, as a citizen—and somewhat more directly than the average citizen—should also be concerned with the larger framework of international association, of which international health must form a part. The future of the world is being decided on the battlefields of Europe and the South Pacific. It is also being decided by deliberations of the chancelleries of Washington and London and Moscow; and these deliberations must be largely guided by intelligent and informed public opinion.

Two books have recently appeared which should materially aid us, in the United States, in the development of such an opinion.

There are two real dangers to be avoided, the Scylla and the Charybdis of international planning. The first of these is hopeless pessimism—which is fostered and reënforced by the sinister influences of special vested interests and narrow isolationism. As an antidote to this trend, *How to Think about War and*

Peace, by Mortimer J. Adler² may be recommended. Mr. Adler looks far ahead. He gives us a blueprint of a world order which he admits may not be reached for five hundred years; but he demonstrates with clarity that such a world order is logical and necessary as an ultimate ideal.

In the United States, wise planning on an international scale is, perhaps, more endangered by undue optimism than by over-pessimism. We are too accustomed to think that Utopia may be attained at one leap by a world conference and the signing of a set of resolutions. Perhaps this point of view is influenced by the common conception that our own Declaration of Independence and Constitution emerged from nothingness by an act of creative imagination. We should remember that these documents represented the distillate of some centuries of democratic experience in the England from which the founding fathers came. Social institutions grow by practice; they do not emerge, like Minerva, full-fledged from the brain of Jove.

To the over-optimist, *How New Will the Better World Be?* by Carl L. Becker³ may be strongly recommended. Professor Becker shows us that nationalism and the concept of the sovereign state, imperialism and power politics, cannot be abolished by resolution. They represent actualities with which we must deal. Yet in his last two chapters, the author indicates how—within the framework of reality—it is possible to do the two essential things—to maintain peace, temporarily by force; and to build gradually but steadily toward those economic adjustments which alone can make peace by mutual consent a possibility.

An article by Forrest Davis⁴ outlined last spring what the author considered to be the post-war international policy of our Government. It is a policy which has not yet been contradicted by any official acts at Washington, and is a policy in essential accord with that outlined by Becker. It involves essentially two things. First and foremost, the peace must be maintained—in the name of the United Nations and in the interest of all of them—but actually by the air forces and navies and armies of the four powers which alone will have armed forces and industrial resources of overwhelming power. There is no reason to believe that the United States and Russia would for a moment consider the abandonment of those powers in favor of an international police force beyond their effective control. There is good reason to hope that the four Great Powers would be ready to use their forces with intelligence and foresight in the common interest.

Parallel with this temporary expedient should go the creation of a fully-representative and democratic assembly of the United Nations (and ultimately of all nations of good will) for the development of international policies and the direction of technical commissions (dealing with agriculture, currency, trade, health, labor conditions and the like). From such a structure, a more closely-knit world order can be evolved, by trial and error and through the development of national confidence in the machinery developed.

Such a solution satisfies neither the extreme isolationist nor the extreme internationalist. It is the middle way, in accord with the educational principles of "learning by doing." It is the immediate hope of a world where, as ever before—"politics is the art of the possible."

TUBERCULOSIS AS AN ECONOMIC PROBLEM

THE specific cause of tuberculosis is the *Mycobacterium tuberculosis*; but the most common factor associated with this disease is the economic one. Whether tuberculosis is considered from the standpoint of the individual, the family, or the community, the financial factor stands out prominently in the blueprints of cause and effect. Therefore, tuberculosis is both a medical and a social problem. It is as sound public economy to provide the necessary medical—and social—services for the control and prevention of tuberculosis as it is to spend public moneys for a safe water supply, proper sewage disposal, and fire and police protection.

It has been estimated that the average case of tuberculosis represents a community liability of approximately ten thousand dollars. It is a fact that less than 6 per cent of the families in which the disease occurs are financially able to meet this cost. Accordingly, the taxpayer is paying the bill for tuberculosis whether he realizes it or not. And yet, failure to give full recognition to the many economic aspects of the disease, as well as the adoption of short-sighted and pennywise public policies, are unquestionably postponing the time when the real cost involved may be further reduced.

Encouraging progress has been made in the control of tuberculosis by the application of epidemiology and clinical medicine. But the benefits would reach farther and last longer if equally effective measures were adopted to remove the common economic barriers associated with the disease. Failure to recognize these barriers, or failure to do something to overcome them, results in waste of effort and waste of social resources. The success which has crowned the efforts to eradicate tuberculosis in cattle has been due largely to the recognition that fundamentally it is an economic problem, to be overcome only by the intelligent expenditure of public funds. Sufficient public moneys should similarly be provided and expended within the framework of democratic processes to meet the individual and family needs in overcoming human tuberculosis.

It is wishful thinking to conclude that the optimum in health protection is being realized from the more than one hundred million dollars invested in public tuberculosis hospitals in the United States and from the millions spent annually for their operation, and for case finding. All too frequently the application of the "means test"—the question of ability to pay—does more than any other circumstance to limit the benefits which should accrue from these expenditures. Patients who accept segregation and treatment in a tuberculosis hospital are acting in the public interest. Except in the case of the very few who are well able to pay for their care, family resources for the essentials of healthful environment should be conserved and no payment should be required. The recent elimination by New York State of all requirements for a financial investigation in the case of patients admitted to county tuberculosis hospitals is an admirable step. Where such a policy is in force we have a situation almost unique in the field of American medicine—the provision of what is essentially the best available medical care in one special field for all citizens of the community.

The greatest profit to the individual, the family, and the community results from the discovery and treatment of the disease in its early stage. The x-ray is essential for early diagnosis, and x-ray facilities must therefore be made readily and universally available for all individuals as an element of a progressive public

case-finding service. From an epidemiological viewpoint it may be just as important to know who does not have tuberculosis as it is to know who has the disease. Consequently, the profit from the liberal use of the x-ray should not be expressed only in terms of cases diagnosed.

Equally fundamental in tuberculosis, and even more commonly ignored or neglected, are the related environmental conditions which contribute to the spread and development of the disease. Of particular importance is the problem of housing. Insufficient emphasis is customarily placed on the need for more healthful living conditions, particularly for families in which there has been tuberculosis. Many families who are financially able to meet the cost of acute illness become impoverished in the face of this disease.

Poverty or the fear of poverty, more than any other single factor, changes the tides of battle in favor of the tubercle bacillus in the individual or the family. Poverty engenders crowding, ignorance, nutritional deficiencies, and medical neglect, all of which create a favorable soil for the tubercle bacillus. The result is that benign infections become malignant, closed or sputum-negative cases become open or sputum-positive cases, the spread of germs becomes constant and massive, and cases multiply.

The essentials of tuberculosis control are early discovery and prompt and adequate treatment and segregation. Anything which prevents the attainment of these objectives impedes progress in controlling the disease. The economic factor is such an obstacle. It is common; it is often serious; it has a profound influence on the development and management of tuberculosis.

The needs are clear. There must be wider and keener recognition of the existence of this barrier to progress, and there must be courageous leadership in the execution of steps for its removal.

New Developments in Health Education*

Public Health Education Section

IN preparing this report the committee did not undertake a detailed survey of our field. It sent out no questionnaires. Instead it relied on informal inquiry addressed to a few people in various parts of the country who presumably would know about outstanding new developments. By this method and while all attention is focused on the war it is not unlikely that many important new things have escaped our attention.

NATIONAL DEVELOPMENTS IN THE UNITED STATES

At the national level one of the most significant developments is the expanded interest of the U. S. Public Health Service. An experimental in-service program conducted for its own employees in Washington has brought it the added responsibility of directing a health education program for all government employees, under Congressional authorization. Stimulated by its leadership many local health departments have begun training of health education personnel and have sponsored courses, workshops, and scholarships in health education for teachers.

During the last two years the Service has directed demonstrations in 90 southern areas on the use of teachers during the summer months for community education for malaria control. The rapidly widening program of education of food handlers pioneered by Texas has received increased impetus through the appointment by the Service

of eight individuals to carry on this program in its regional districts.

Perhaps the greatest new development in health education, measured in terms of dollars spent and people reached, has been in the field of nutrition. Under the leadership first of the Office of Defense Health and Welfare Services and later the Food Distribution Administration, the nutrition program has had the participation of many government offices, state and local official, and unofficial agencies and commercial organizations. There must be few people in the United States upon whom its educational message has not impinged. Incidentally, this program also has set an interesting pattern for the utilization of the vast resources of business for health education under government direction.

Another war-born federal activity is the Physical Fitness Program under the leadership of the Federal Security Agency in cooperation with other federal agencies.

A program that has great implications for the future is that of the Federal Public Housing Authority. This agency has appointed a Director of Health Education and is urging its Project Service Advisers to assist with the development of health education programs in the housing projects.

The committee has not attempted to review the extensive programs of the Army, Navy, Office of War Information, Office of Foreign Relief and Rehabilitation Administration, and other

* COMMITTEE ON NEW DEVELOPMENTS IN HEALTH EDUCATION
Organized 1942.

wartime agencies. It should be noted here, however, that as a result of the work of these agencies millions whom our health education efforts have only lightly touched in the past are now being reached with health education through newspapers, periodicals, pamphlets, movies, radio, and in classes all over the world.

Among the national voluntary agencies an outstanding development is the study by the National Health Council which is nearing completion. This study reached into many communities and its report should have a wide effect in sensitizing the country to the needs and opportunities for health education.

During the past year or two the contributions of business and industry have noticeably increased, particularly in the field of nutrition education.

Under new direction the National Safety Council and its local affiliates have stepped up programs on safety education, aided by industry, the War Production Board, and other government agencies, and special projects, such as the unique Safety Zone Program of the Zurich Insurance Companies.

STATE PROGRAMS

Several interesting developments have occurred in the states. Florida and Illinois have created large autonomous state-wide Public Health Committees. Nebraska and Pennsylvania and Utah have set up local Health Assemblies. California has sponsored local Health Institutes. Illinois, Indiana, Oklahoma, and North and South Carolina, among others, have initiated programs of training health education personnel for their health departments. Other states in other ways give evidence of increased appreciation of the necessity for health education under trained direction in any well rounded public health program.

LOCAL PROGRAMS

Of far reaching importance is the growing movement for organized citizen interest in community health activities. Sometimes stimulated from above, but frequently arising from forces within the community, this stirring at the grass roots gives great hope for a wide support of all health activities in the future. Noteworthy developments have occurred in Boston, New York, Hartford, Bridgeport, Detroit, and in local areas in North Carolina, South Carolina, and Oklahoma.

MATERIALS

Out of these many programs and others there has come a wealth of new materials for our use, much of it better than ever before. Leaflets, pamphlets, exhibits, radio scripts and, in a few instances, films are being designed for particular groups using appeals to reach people in new kinds of work, new communities, new conditions of marketing, budgeting, and living. A healthy sign in a time of strain is the somewhat more frequent use of humor, a useful but sometimes dangerous tool. There is evidence of increasing collaboration among interested groups in the preparation of materials, such as that between health and mental hygiene workers, and between tuberculosis workers and public health nurses. There is also more emphasis on securing editorial help from mothers and others for whose use materials are being planned.

Key sources of new material are:

The Cleveland Health Museum for exhibits
The U. S. Public Health Service, particularly for posters and pamphlets

The U. S. Department of Agriculture, regional offices of the *Food Distribution Administration* and state and local *Nutrition Committees* for a wide variety of nutrition materials including lists of additional sources

The U. S. Office of Education for publications on the Physical Fitness Program prepared in coöperation with the Army, Navy, U. S.

Public Health Service, and the Office of Community War Services

The U. S. Children's Bureau for information on the free Emergency Maternity and Infant Care Program for wives and babies of enlisted men

The U. S. Department of Labor and the *National Safety Council* for materials on Safety in the Home, on the Farm and on the Job

The Planned Parenthood Federation of America for materials on family planning in relation to public health

The American Film Center for a new and excellent annotated list of health films for lay audiences

For other references to materials, books, and programs, Section members are referred to the monthly "Credit Lines" in the *American Journal of Public Health*, and *Channels*, published by the National Publicity Council. Among the important new books are Dr. Nyswander's *School Health Problems*, the Report from the American Museum of Health on "What the Public Knows About Health," and the American Association of School Administrators' *Health in Schools*.

A dramatic expression of the re-awakened interest in health exhibits is the "Healthmobile" of the Brooklyn Tuberculosis and Health Association which is on display at this meeting.

PERSONNEL TRAINING

Keeping pace with the expanding horizons of health education, colleges and universities have accelerated and modified their educational programs. As a background they now have available the "Proposed Report on the Educational Qualifications of Health Educators."* This stresses the importance of field experience and "internship" and mentions the place for graduate training. Although most schools have always offered some "field work" as part of their training in health education, the actual development of special field training courses

originated as part of the health education program which began in September, 1941, when the U. S. Public Health Service in coöperation with the North Carolina State Board of Health launched the first of a series of demonstrations in community health education in war counties. To meet the demand for personnel which these demonstrations created, fellowships were provided by several state health departments and the W. K. Kellogg Foundation to send trainees for graduate work to the School of Public Health at the University of North Carolina beginning in March, 1943.

A second grant to the U. S. Public Health Service from the W. K. Kellogg Foundation has made it possible for Yale and the University of Michigan also to offer this broader training in health education. Grants for health education fellowships have also been offered by the Commonwealth Fund and the Institute of Inter-American Affairs.

In connection with grants from the latter organization the newly created School of Public Health at the University of California plans to offer a special course in Health Education to meet the needs of Latin Americans. Meantime it is to be regretted that the Health Education course at the Massachusetts Institute of Technology which has trained so many of our leading health educators will be discontinued next year.

DEVELOPMENTS IN CANADA

The Health League of Canada reports that it has initiated this year a National Immunization Week with large-scale sponsored advertising, poster distribution, and nation-wide radio hook-ups. It has also embarked on an extensive Industrial Hygiene program in coöperation with Canadian Industries. In the Province of Quebec it has sponsored a campaign for a province-wide pasteurization law.

* *A J.P.H.*, 33, 8:998 (Aug.), 1943.

FOREIGN DEVELOPMENTS

In the Office of the Coördinator of Inter-American Affairs there have been established sections both on Health Education and School Health Education, and a program for Latin America, embracing training in this country and in Latin America, demonstrations and health education activities is now under way from that Office. In connection with these programs there was held on October 11 what may prove to be only the first of a series of Inter-American Conferences on Health Education.

From England there has arrived this year the first issue of a new quarterly *Health Education Journal*, published by the Central Council for Health Education, which it is interesting to note provided the weekly periodical *Index of the National Health Library* with a full column of material on health education for the first time in its history.

SUMMARY

These brief highlights demonstrate unmistakably that health education is a lusty adolescent which is earning and receiving a larger place in the family of public health specialties. It is clear, too, that the war has emphasized the need for health education and has given it means to expand.

Some of the governmental agencies responsible for post-war planning have

requested plans for an adequate health education program after the war. It might be well for the Section to appoint a committee to work on such plans now and thus make available the experience of the profession for any plans that may be devised.

The committee regrets that there is not time to describe in some detail many of the various programs, projects, courses and materials which have been referred to, or to mention the splendid continuing programs of the scores of national and local official and voluntary agencies. It was frequently difficult to decide whether or not a development was "new." Being under a mandate from the Section to keep our report short, we have no doubt erred in the direction of omission. There must be many whose important contributions have been neglected in this brief compendium of new highlights. The committee asks their indulgence in view of Annual Meeting program limitations. Recommended additions to the report will be welcome.

The committee acknowledges the valuable contributions it has had from Drs. Coffey, Derryberry, Horning, Platt, Bauer, and Bates, and Mrs. Walsh and others in compiling its material.

HOMER N. CALVER, *Chairman*

LUCY S. MORGAN, PH.D.

KATHERINE Z. W. WHIPPLE

Report of the Archivist, 1943

Laboratory Section

NOTICE of honors and awards to members of the Section have appeared frequently in the literature during the year. Dr. John R. Mohler, Chief of the U. S. Bureau of Animal Industry, retired after twenty-six years' service. He has been awarded many honorary degrees and prizes during this time; the most recent, the Alumni Reward of Merit at the Founders' Day ceremonies on January 16 at the University of Pennsylvania.¹

Charter and early members of the Section continue to be nominated for their distinctive services. Dr. Samuel Gate Prescott was awarded the Nicholas Appert Medal by the Institute of Food Technologists for his valuable contributions in the field of food technology, especially to the progressive development of food manufacture and processing. Since his retirement in June, 1943, as Dean of Science of the Massachusetts Institute of Technology, he has been called into consulting service by the Dehydration Committee of the U. S. Department of Agriculture.²

Brigadier General Frederick F. Russell, retired, was awarded the recently created Gorgas Medal for "exceptional meritorious service to preventive medicine for our armed forces," by the Association of Military Surgeons of the United States on December 15, 1942.³

The Maritime Commission has honored the small group of medical men who in earlier years made Johns Hopkins University famous throughout the world, by giving their names to new Liberty ships.⁴ Dr. Welch's services are memorialized in the ship "William Welch."

The death of the following members and fellows is recorded with deep regret:

Frank C. Rainier

Whittier, Calif.

Elected Member 1940

James M. Brannon, Ph.D.

Urbana, Ill.

Elected Member 1929

Clarence N. Boynton

Phoenix, Ariz.

Elected Member 1916. Elected Fellow 1935

Charles R. Hoover, Ph.D.

Middletown, Conn.

Elected Member 1930

During the year the 1,018 members of the Laboratory Section were canvassed so that there might be as complete a record as it is possible to make at this time of the services and activities of the individuals and the Section in relation to the war. The 358 replies indicate the solid contributions of the laboratory to the medical and public health problems of the war period and to the educational and post-war situations.

The replies were examined by groups, that is, those from members in the universities and research institutes, in governmental service—from federal to municipal organizations — commercial and private laboratories, hospitals, and the Army or Navy, either in regular service, or under enlistment for the present war.

Enumeration of services and activities could have no statistical value, since the returns are not complete nor, as was expected, has it always been possible to state the specific project under investigation. These records do show, however, how extensively estab-

lished laboratory services have been utilized and that competent investigators are making important contributions to the varied and urgent practical needs of the war.

The greatest number of replies (83) is from the university-research-institute group. The number of projects directly related to the war is also highest in this group. Members are serving on the committees for the Investigation of Epidemic Disease of the Army and are consultants to the Secretary of War and to the U. S. Public Health Service. Under the Committee on Medical Research of the Office of Scientific Research and Development they are also engaged as Consulting Investigators or Responsible Investigators on specified and unspecified projects. Others are in active military service, frequently in highly responsible positions. The special war research projects at the universities are in practically all instances added to accelerated teaching schedules. In several instances the colleges have collaborated as units of the Army or Navy.

Twenty-three replies were received from members of the Section in government laboratories in the United States, Alaska, Hawaii, Canada, Jamaica, Mexico, and Puerto Rico. The variety and range of responsibilities and undertakings make this group alone a miniature American Public Health Association.

The official health departments of only 25 states and 3 Canadian provinces are represented in the replies to the canvass; but 62 replies were received from these 25 states. The flexibility of organization and the personal contributions that have made it possible to assume much added work, while at the same time there has been a serious loss in trained personnel, appear in this group. Members of the state and provincial laboratories are also among the consultants to the War Department,

and they collaborate with the Area Service Command Laboratories by instructing medical personnel in laboratory procedures. State gas officers and gas consultants have also been selected from the staffs of the state laboratories.

Reports from members in 49 county and city laboratories in the United States and Canada, like those in state and provincial laboratories, show them to be carrying heavily increased schedules in all services. While members in the federal and state laboratories are seen from their reports to be engaged in policy-making and administrative phases of war work, those in the smaller local units participate immediately in the medical, public health, and sanitary problems of civilian protection and education. Members in the large city laboratories, however, are also represented in the national consultantships and war agencies.

The demands on maintenance and operation that are made on the outlying laboratories are illustrated in a reply from the Branch Laboratory at Anchorage, Alaska. The acting director reported the "designing and equipping of a two-unit portable laboratory for use in epidemiological field work; the laboratory can function away from any base for one month and has supplies for handling 400 contacts. The whole weight of 2 units is 200 pounds; both are designed for easy handling and rapid transportation."

The 54 replies from commercial and private laboratories record important and extensive research and service both in civilian and war needs, in medical, veterinary and agricultural projects, in dairy research, chemical warfare, and industrial hygiene.

Thirty-three replies from members with hospital affiliation list active participation in civilian medical service, blood donor service, and important research by Responsible Investigators under the Committee on Medical Re-

search of the Office of Scientific Research and Development.

Forty-two replies show only present Army or Navy affiliations, but they list the responsibilities that are associated with titles ranging from that of Assistant Medical Technician to Brigadier General.

The canvass has thus produced for the archives a record of the activities in this war period of more than one-third of the membership of the Section. The pattern of medical and health services to the nation is interestingly shown in the responses from members in all grades of government and hospital

service. Valuable contributions have also come from their researches. Private laboratory enterprises are seen to augment the government organizations in a remarkable way. Members in universities and research institutes show significant contributions in a splendidly coördinated plan of investigation, which has a counterpart in the practical applications made under the direction of the Army and the Navy.

Examination of Water and Sewage^{*}

Laboratory Section

THE following changes in bacteriological analysis of water, by the Standard Methods Committee on the Examination of Water and Sewage, which have been made in manuscript are submitted for your consideration:

1. The introduction of medium formulae for tryptone glucose extract agar and lauryl sulfate tryptose agar. The elimination of formulae for crystal violet lactose broth and fuchsin broth.

2. The introduction of methods for treating sample bottles with sodium thiosulfate and recommendation that chlorinated waters be collected in thiosulfate-treated bottles.

3. The introduction of tryptone glucose agar as an alternative to nutrient agar for plating water samples.

4. The term "coliform" be used to replace "coli-aerogenes" throughout the text.

5. The introduction of the following paragraph concerning media for the presumptive test:

"In these standard tests lauryl sulfate tryptose broth may be substituted for lactose broth in the examination of all waters except final filtered, treated and filter-treated waters. It may be substituted for lactose broth also in the examination of final, filtered, treated

and filtered-treated waters provided the laboratory worker has amply demonstrated by correlation of positive completed tests (isolation of coliform organisms) secured through the use of lauryl sulfate tryptose broth with those secured through the use of lactose broth, in the examination of such waters, that the substitution results in no reduction from the density of coliform organisms indicated by the standard procedure using lactose broth."

6. Brilliant green lactose bile broth is the only liquid confirmation recognized. Fuchsin lactose broth, crystal violet lactose broth and formate-ricinoleate broth have been dropped as confirmatory media. Formate-ricinoleate broth can still be used in the completed test for detecting spore-forming bacilli.

The incubation period for brilliant green bile broth shall be 48 ± 3 hours at 35° - 37° C.

STANDARD METHODS COMMITTEE ON EXAMINATION OF WATER AND SEWAGE

Organized 1899. Reorganized 1933. Published reports: *Year Books* 1930-1931, 1934-1935, 1935-1936, 1937-1938, 1939-1940, 1941-1942, *A.J.P.H.*, May, 1943. 8 volumes published: 1905, 1912, 1917, 1920, 1923, 1925, 1933, 1936.

Examination of Germicides and Antibacterial Agents*

Laboratory Section

THE Report of the Standard Methods Committee for the Examination

tion of Germicides and Antibacterial Agents comprises separate progress reports from the several Referees and Associate Referees.

* Committee authorized 1941. First published Report *A.J.P.H.*, 33, 5:602 (May), 1943

STUART MUDD, M.D., *Chairman*

Antibiotic Agents

Considerable progress has been made during the year on the formation, nature, and utilization of antibiotic substances produced by microorganisms. Some of the more significant results can be summarized as follows:

Penicillin, the most important antibiotic agent so far isolated, is now being produced in this country by 15 to 20 industrial organizations. The material can be used very effectively in the treatment of pneumococcus, streptococcus, and staphylococcus infections, some of which are resistant to the action of the sulfonamides. Progress has been made not only in the mass production of the penicillin, but also in our knowledge of its chemical nature and in its mode of action. Tyrothricin, produced by *Bacillus brevis*, has found extensive use in the treatment of mastitis in cattle, and in topical application in certain human infections.

Several new antibiotic agents have been isolated recently. *Penicillium notatum* was found to produce, in addition to penicillin, another factor, designated as *Escherichia coli* factor, penatin, notatin, and penicillin B. This is an oxidative enzyme, protein in nature,

and active in the presence of glucose; its activity is neutralized by catalase. *Aspergillus flavus* was shown to produce two active substances: (a) aspergillic acid, that acts against both Gram-positive and Gram-negative bacteria, and (b) flavicidin, similar in every respect to penicillin. Streptothricin, produced by *Actinomyces lavendulae*, is a basic substance; it possesses limited toxicity and is active against Gram-negative as well as Gram-positive bacteria. Proactinomycin, isolated from *Proactinomyces gardneri*, is also a base, but it is active largely against Gram-positive bacteria.

Among the other substances recently isolated from microorganisms, it is sufficient to mention clavacin, fumigacin, claviformin, and penicidin. They differ in toxicity to animals and in their activity, some being active largely against Gram-positive bacteria, and others are active both against Gram-positive and Gram-negative bacteria. Very little is known concerning their chemical nature.

Associate Referee

Chemical Antiseptics

For the development of methods for testing antiseptics, associate referees have been appointed who are currently at work on various phases of the methods for testing antiseptics. The preliminary work that is now under way concerns the development of a medium for use in *in vitro* testing of antiseptic substances. This investigation is directed toward the development of a medium which will give constant results in the hands of different laboratory workers, particularly in the control of the resistance of the organisms to be used in the test.

Work is also under way on a study of the resistance of different types of organisms which are being considered for use in *in vitro* tests. It is contemplated that eventually in such tests we will utilize not only staphylococci, but possibly streptococci, coliform, and pseudomonas types as well. Through study of the resistance of different species of organisms it will be possible to bring out more clearly the inherent specificity of most germicidal compounds.

The *in vitro* testing of antiseptics is only a preliminary step in determining their efficacy, since the clinician is mainly interested in what an antiseptic is capable of doing under the actual

conditions of use. Investigations are planned which will give us methods for determining the efficacy of germicides under the conditions of use in or on the human body. Such tests will include toxicity tests, both *in vitro* and *in vivo*, with the thought in mind that the value of the *in vitro* test lies mainly in its ability to eliminate the inefficient antiseptics, and the true worth of an antiseptic is only elicited through a study of it as near the actual conditions of use as it is possible to obtain.

Investigations are planned to include a study of the efficacy of germicides in the destruction of spores, particularly of the genus *Clostridium*, as they relate to those preparations offered for use for cold sterilization of surgical instruments. In connection with this, it should be pointed out that the referees involved in the investigations dealing with antiseptics and disinfectants plan to work closely together since the study of antiseptics, disinfectants, and fungicidal substances are so closely interrelated.

The associate referees on antiseptics met during these sessions to discuss plans for the investigations to be carried out during the coming year.

HENRY WELCH, *Referee*

Chemical Disinfectants

Restrictions on allotments of phenol and cresol for use as disinfectants have led, during the past year, to very great increases in the relative and gross amounts of synthetic preparations now being offered as disinfectants.

At the St. Louis meeting of this Association, a paper was read pointing out that in the case both of certain synthetic disinfectants and the more familiar coal-tar type, containing synthetic wetting agents, the conventional

phenol-coefficient method of evaluating germicidal power may give widely divergent and deceptive results. During the year expressions of dissatisfaction with the F.D.A. phenol-coefficient method as a test for modern disinfectants have been received from several sources.

In the face of this urgent situation a subcommittee on disinfectants has been formed to study means of improving germicidal tests for these compounds.

Members of the subcommittee have been selected from a wide field and represent the manufacturers, the commercial examiners, academic, and government control interests in the problem.

Difficulties in the present procedure arise from the fact that the sensitivity of the test organisms, *Eberthella typhosa*, to certain germicidal substances is altered when it is cultured in media containing peptone of slightly different composition. The effect is not detectable by the organisms' reaction to phenol, i.e., by the phenol control. Other microorganisms such as *Pseudomonas aeruginosa* and *Escherichia coli* are relatively insensitive to these variations in the peptone. Three distinct approaches to the problem have been recognized as corrective possibilities and investigation on the three has been

initiated. Dr. Mallmann of Michigan State College has instigated an endeavor to obtain a less unstable if not a constant strain of *Eberthella typhosa* or closely related organism suitable for use. Work on the resistance of a number of strains of *Pseudomonas aeruginosa* and *Escherichia coli* which might be used for testing purposes was commenced during the year. Efforts to locate a source of peptone of constant composition suitable for the culture medium have been under way for some time.

Information from the newly appointed associate referees indicates that the subcommittee is anxious to accomplish the work necessary to recommend improvements in the present testing procedure; and I feel that it may be in a position to do this within the forthcoming year.

C. M. BREWER, *Referee*

Detergents

The development of cationic and anionic wetting agents with germicidal or bacteriostatic properties opens a new field of application for detergents. There have appeared on the market a number of detergent-sanitizers in the past that upon investigation were found to be wanting both as good detergents and as sanitizers. To date the writer, upon investigating the claims of these products, has been unable to justify

their uses. Several cationic compounds when mixed with detergent mixture offer marked possibilities as detergent-sanitizers that have practical applications. The writer expects to spend considerable time in the development of such products during the coming year. The past year the writer has been doing exploratory work on detergent-sanitizers and their practical usefulness.

W. L. MALLMANN, *Referee*

Disinfection of Air by Germicidal Vapors and Mists

Recent developments in the field of air sterilization with glycol vapors have shown that triethylene glycol is the most potent bactericidal and viricidal agent yet found.¹ This substance is highly lethal in concentrations of 1 gm. of the glycol dispersed in 200 million

ml. or more of air for the respiratory pathogens and influenza virus. Toxicity tests on triethylene glycol consisting of maintaining monkeys and rats for many months to a year in an atmosphere saturated with this substance have revealed no deleterious

effects. Likewise the long continued ingestion of this substance has had no detectable harmful action.

Investigation of the various conditions which affect the germicidal activity of glycol vapors has shown that atmospheric humidity is of marked importance; a minimum of 35 per cent relative humidity being essential for the killing of dust-borne bacteria.² Practical application of the use of glycol vapors for the purpose of controlling air-borne infection has had to await the construction of suitable apparatus for the dispersion of glycol vapors into

large enclosed spaces and the development of an instrument to control automatically the concentration of glycol vapor in the air. Rapid progress is being made in the solution of both these problems. Reports of the use of propylene glycol vapor in a children's hospital suggest that it was effective in reducing the incidence of acute respiratory infections.³

Disinfection of Air by Ultra-violet Irradiation

A number of publications have appeared on the usefulness of upper air irradiation in the control of cross-infection in children's hospitals and infant wards. It appears that the use of ultra-violet irradiation of operating rooms and nurseries is now well established.

No publications are available on the application of ultra-violet irradiation in the control of air-borne infection in sleeping quarters. Such information is urgently needed since the crowding of men in large sleeping halls may require a quick decision on the possible use of ultra-violet irradiation in stopping cross-infection in military establishments.

Recent publications have again emphasized the importance of dust and lint as possible carriers of micro-

organisms. Upper air irradiation would destroy only microorganisms and virus particles which come into the range of intense radiation. The use of floor irradiation has been suggested. The installation of fixtures for floor irradiation appears to be a relatively safe procedure since in general many floors have low reflecting power for ultra-violet radiation.

A new acceptance of ultra-violet irradiation for the purposes of disinfecting air has been published by the Council on Physical Therapy of the American Medical Association (*J.A.M.A.*, 122: 503-504, 1943). It is important to point out that anyone who is planning to install ultra-violet sources for air irradiation should study this acceptance most carefully.

Associate Referee

Fungicidal and Fungistatic Agents

The Subcommittee on Fungicides is engaged in a critical examination of methods now used in fungicide testing. Comparative studies so far made have

suggested that some of the technics in use should be modified but the subcommittee is not yet ready to recommend specific changes.

TEST ORGANISM

It has been found that a fungus carried under the name "*Trichophyton rosaceum*" and widely used as a test organism is actually a species of *Fusarium*. This is a saprophytic fungus unrelated to dermatophytosis. Attempts so far made to obtain an authentic culture of *Trichophyton rosaceum* have failed and it is concluded that the name has been incorrectly used in the reports of fungicide testing. The dermatophyte correctly designated *T. rosaceum* is, in any case, unsuitable for use as a test fungus because of its slow growth and sparse sporulation.

The selection of one or more fungi to be used as standard test organisms will require further comparative studies. So long as the fungicides to be tested are intended primarily for use against dermatophytosis, it is reasonable to select a dermatophyte. Of the three important genera of dermatophytes, *Trichophyton* is most important in the etiology of dermatophytosis of the foot and is also most suitable for use as a test fungus. The strain of *Trichophyton* selected should be stable, produce many conidia (spores), produce conidia of only one type (unicellular and of

uniform size), allow preparation of a uniform suspension without clumping and without formation of surface films, and have a satisfactory resistance to heat or a standard fungicide. Many strains of dermatophytes will not meet these requirements. The strain chosen should be accurately described in terms of colony appearance, morphology, and resistance so that another strain can be substituted if the original is lost or becomes unsuitable for use. Stability in the dermatophytes is only relative. Any strain chosen will quickly and certainly mutate to produce an inferior strain unless it is frequently transferred and refrigerated between transfers.

TECHNIQUES

Specific problems of technic now being investigated include: the medium to be used, the selection of a suitable peptone, the relative advantages of liquid and agar media for production of conidia, methods of preparing a conidial suspension, proper density of conidial suspension, intervals of exposure, methods of withdrawal of sample, best type of medium for subculture of exposed sample, and selection of a suitable fungicide for standard comparison.

Stillbirth and Maternal Mortality Rates*

Vital Statistics Section

THE Subcommittee on Maternal, Stillbirth and Infant Mortality has been set up to consider "the best method of computing Maternal Mortality . . . problems of stillbirth registration and the best method of stating the rate." †

This preliminary report is limited to general considerations of the stillbirth rate and to one method of supplementing the maternal mortality rate. The broader aspects of the problem of stillbirth registration and of the different kinds of measures for maternal mortality require more extensive and elaborate investigations, which the subcommittee hopes to continue.

STILLBIRTHS

Definition—The Model Vital Statistics Act ‡ recommends the following definition: "Stillbirth means a birth after at least twenty weeks of gestation in which the child shows no evidence of life after complete birth." "Evidence of Life" is further defined as follows: "The words 'Evidence of life' include heart action, breathing, or movement of voluntary muscle." The laws of only one-half of the states are in complete agreement with the above definition. The laws of the other half of the states and of the District of Columbia differ from the above definition in one or the other of the two criteria. Nine of the states are not in accord with the Model Act in the definition of "evidence of life." Fourteen

states and the District of Columbia differ from the Model Act in their requirements of the minimum period of gestation. One state is not in accord with the Model Act in either of the two criteria.

The minimum period of gestation at which registration of stillbirths is required is the more important of the two criteria in terms of the inequality of stillbirth registration in the different states. In 3 states and in New York City the minimum period of gestation required for stillbirth registration is less than 20 weeks. Five states require registration only if the fetus is advanced at least to 28 weeks of gestation. In the remainder of the states which are not in accord with the Model Vital Statistics Act, the period varies between 20 and 28 weeks.

It is to be expected that the differences in the definition of stillbirths are directly related to the relative number of stillbirths that are registered in the different states. For example, the stillbirth rate in 1940 varied from 16.4 per 1,000 total births in the State of Washington (requirement for registration—"advanced beyond the seventh month") to 49.4 in New York State (New York City requires the registration of all products of conception).

Because of this inequality in stillbirth registration, the Bureau of the Census restricts the amount of detail which it tabulates from the stillbirth certificates. It is also primarily for this reason that the Bureau of the Census bases the stillbirth rate on live births rather than on total births (live births and stillbirths) on the theory that the ratio of stillbirths to live births

* Report of the Subcommittee on Maternal, Stillbirth and Infant Mortality, of the Committee on Statistical Practice, organized in 1941.

¹ The law for New York State (Exclusive of New York City) is in accord with the Model Vital Statistics Act.

does not convey the impression of a rate which presumably measures risk.

It is difficult to evaluate the differences in the stillbirth rates of the various states in order to determine whether these differences are real and to what extent they are the results of the inequalities in the definition of stillbirth. The committee attempted to obtain at least a partial answer to this question by comparing the stillbirth rates of the various states with the neonatal mortality rates (see table). These two rates are influenced by the same general group of congenital and environmental factors. It may therefore, be expected that, by and large, the variations of the stillbirth rate in the different states would be similar to those of the neonatal mortality rate. A large excess in the variation of the stillbirth rate over that of the neonatal mortality rate would indicate the effect on the stillbirth rate of the inequalities in the provisions for the registration of stillbirths in the different states. Indeed, it is seen that generally the stillbirth rate is larger in those states in which the required period of gestation is smaller. For example, for the group of 32 states whose laws are in accord with the Vital Statistics Act the stillbirth rate is practically the same as the neonatal mortality rate; for the 4 states in which the minimum period of gestation is less than 20 weeks, the stillbirth rate is considerably higher than the neonatal mortality rate, and for the 13 states which require the registration of stillbirths only at periods of gestation of more than 20 weeks, the stillbirth rate is lower than the neonatal mortality rate. However, a comparison in the individual states between the neonatal mortality and the stillbirth rates reveals that the differences are almost as large among the 32 states which are in accord with the Model Vital Statistics Act, as among the remaining states. Moreover, with the

exception of a few states which require the registration of all products of conception, the total range of variation of the stillbirth rate by state is not much different from that of the neonatal mortality rate.

The conclusion that may be drawn from this table is: (1) that we are approaching relative uniformity in the registration of stillbirths, and (2) that a large part of the inequality existing in stillbirth statistics is the result of the different legal requirements for registration. This latter may to a large extent be eliminated by different procedures in the tabulation of stillbirths.

Improvement in the comparability of stillbirth statistics in the various states may be accomplished even before all the states attain uniformity of definition. For example, only stillbirths stated to be of 20 weeks or more gestation may be included in the stillbirth tabulations. It is also possible to publish two distributions of stillbirths: one to include all those of at least 20 weeks gestation and the other to include only stillbirths of 28 or more weeks of gestation. This latter distribution would not only provide a uniform basis for comparing the stillbirth rate of the different states but would also be useful in computing the maternal mortality rate (see discussion on maternal mortality).

The subcommittee recommends:

1. That states whose laws are not in accord with the Model Vital Statistics Act make every effort to change their laws and regulations to conform with the Model Act with respect to the criteria "evidence of life" and "minimum period of gestation" and thus attain uniformity of definition in all parts of the country;

2. That until such uniformity of definition is attained the Bureau of the Census and the individual states omit from their tabulations all stillbirths stated to be of less than 20 weeks gestation;

3. That the Bureau of the Census experiment with the statement of period of gestation on the stillbirth certificates with a view of publishing an additional distribution, con-

sisting of all stillbirths of 28 weeks or more gestation;

4. That the stillbirth rate published by the Bureau of the Census and by the individual states be based on total births (live births and stillbirths) rather than on live births;

5. That the statistics on stillbirths published by the individual States contain a distribution of the stillbirths by weeks or months of gestation.

MATERNAL MORTALITY

It is common knowledge that the maternal mortality rate is not, in a statistical sense, a rate at all. It does not measure the risk of death associated with the function of reproduction, since the numerator of the fraction, the number of deaths, is much more completely specified than the denominator, the number of women exposed to the risk of dying in this way, because of the incomplete enumeration of abortions. The maternal mortality rate, therefore, always overstates the risk of death associated with the function of reproduction.

If this overstatement were of uniform magnitude in all parts of the country, and under all circumstances, it could be used as a satisfactory substitute. However, it is well known that the frequency of abortions is not uniform throughout the country. For example, it is greater in urban than in rural areas. It may be more frequent in some hospitals than in others. In evaluating public health services the maternal mortality rate is also often misleading because of the inequality in the frequency of abortion cases. For example, nursing home delivery services are restricted to periods of gestation when the offspring is viable. Again in evaluating prenatal clinic services, it must be remembered that a large proportion of the cases make their first contact with the clinic late in pregnancy and consequently are not exposed to the risk of abortion. The mortality experience in such groups cannot be compared to the usual maternal mortality

rate; yet it is common practice, for lack of a better index, to use the maternal mortality rate for such purposes.

For a complete discussion of the casualties associated with pregnancy and the puerperium, it would be necessary to have, in addition to complete registration of births and stillbirths, also a detailed account of all abortions that have occurred in a given time. Such registration is of course, not feasible. It should, however, be possible to supplement the maternal mortality rate with another index, which is a fairly adequate measure of the risk of death associated with the delivery of a viable offspring. Such an index is made possible by the 1938 revision of the *International Lists of Causes of Death*, which affords a classification of puerperal deaths in four groups as follows:

1. Those associated with abortions (less than 28 weeks gestation)
2. Deaths resulting from ectopic gestation
3. Those in which death occurred without expulsion of the fetus
4. Deaths which follow the delivery of live or stillbirths (28 weeks or more gestation)

This latter group obviously is directly related to the number of women who were delivered of live or stillbirths. The ratio of deaths following the delivery of a live or a stillbirth to all women who are delivered of live or stillbirths is a measure of the risk of death associated with the delivery of a viable offspring, and is more nearly a measure of the risk of death associated with the function of reproduction than is the maternal mortality rate. It should be a useful index in connection with maternal health problems and form a uniform index suitable for comparison between various localities and different services.

This index could not and should not replace the maternal mortality rate because of the omission of a relatively large proportion of the maternal deaths,

but it can be very useful as a supplement to the maternal mortality rate.

In order to avoid confusion with the term "Maternal Mortality Rate," it has been suggested that the deaths of mothers who were delivered of a live or stillbirth related to all mothers who were delivered of live or stillbirths be referred to as "Puerperal Fatality Rate." This expression, "Puerperal Fatality," appears to have certain advantages. It has the same meaning as the usual "Case Fatality Rate" in the sense that it measures the mortality among a group of people, all of whom were exposed to a given risk. It also parallels the meaning generally applied to a case fatality rate in that it is restricted only to the length of time in which the condition or risk exists, whereas a mortality rate implies the risk of dying from any condition within a specified period of time usually expressed on the basis of a year.

There is an unfortunate discrepancy in the official definitions of abortion. The Model Vital Statistics Act as stated above, defines "stillbirth" as that of a birth after at least 20 weeks of gestation, which implies that all births of dead fetuses of 20 weeks or more gestation are stillbirths and those of less than 20 weeks gestation are abortions. In the classification of maternal deaths, on the other hand, the definition of abortion is given as of less than 28 weeks of gestation. Consequently all stillbirths between the 20 and 28 weeks of gestation are considered stillbirths by the Model Vital Statistics Act and abortion according to the *International List of Causes of Death*.

If the recommendations made above in supplementing the stillbirth rate by a tabulation of stillbirths of 28 weeks gestation and over are carried out, it would also assist in bringing into accord, at least in practical applications, the two definitions of abortion. The puerperal fatality rate may then relate

the total number of deaths associated with the delivery of a live or stillbirth (28 weeks of gestation and over) to all live births plus stillbirths of 20 weeks gestation and over.

The Bureau of the Census bases the maternal mortality rate on live births. The reason, as in the case of the stillbirth rate, lies in the incompleteness of stillbirth registration. However, many states use total births as the basis for computing maternal mortality and stillbirth rates. It would appear desirable to establish uniformity also in this respect. Because stillbirth registration is improving throughout the country and especially because maternal mortality associated with the delivery of a stillbirth is very much higher than that associated with the delivery of a live birth, it appears desirable to use total births (including stillbirths), as a basis for computing maternal mortality rates.

The recommendations of the subcommittee can be summarized as follows:

1. That the maternal mortality rate be based on total births (live births and stillbirths).
2. That in addition to the maternal mortality rate the Bureau of the Census and the individual states publish also puerperal fatality rates, that is, deaths of women who are delivered of live or stillbirths (28 weeks of gestation and over), related to the total number of deliveries of live and stillbirths (28 weeks of gestation and over).
3. In view of the high correlation between survival of mother and survival of offspring, it is recommended that the individual states publish additional details on the puerperal fatality rate. It is desirable to show the rate associated with the delivery of live births separately from that associated with the delivery of stillbirths. This can be accomplished by a process of matching the maternal death certificate with that of the infant's birth or stillbirth certificate.

Milk and Milk Products

(Milk, Cream, Butter, and Cheese)

Laboratory Section

THE war emergency has caused many milk control officials to make a special study of milk control procedures. Fortunately the foundations laid by the Milk and Milk Products Committee in the past have been laid so well that the methods outlined in the present Eighth Edition of *Standard Methods for the Examination of Dairy Products* have proved adaptable to all of the emergency situations that have arisen. Thanks to the survey made by Dr. Black (see *A.J.P.H.*, 33:824-832, 1943), there has been increased interest in a real standardization of laboratory technic. This is a highly desirable development.

Because the Army and Navy have practically required the use of pasteurized milk, the milk control program is becoming based even more firmly on the phosphatase test. The fact that the efficiency of pasteurization can be checked so accurately in the laboratory has lessened the necessity for actual time-consuming inspections of equipment, and methods of using equipment in pasteurizing plants. There has been difficulty because inadequately trained workers place a significance on positive findings for coliform organisms that is not justified. The preferred medium for milk testing is sodium formate ricinoleate lactose peptone broth.

The Subcommittee on the Methylene Blue Reduction and Resazurin Tests

have been active during the year. Studies made under the supervision of C. A. Abele, Ch.E., Chairman, show that the variations in dye content that are found in the methylene blue tablets now on the market are not large enough to effect results significantly. Moreover, this subcommittee has recommended the establishment of a standard of approximately 9.0 mg. of dye in each 0.5 gm. tablet. This amount of dye will increase the intensity of the color slightly, but not enough to make a real change in the results secured. Dr. C. K. Johns who has studied the resazurin test reports that a 10 minute resazurin test has been adopted for official grading of market milk in Britain. However, in this case, the test is applied only to raw milk which the intake man suspects is not of satisfactory quality. Dr. Johns feels that any milk so near souring that it will cause a marked dye reduction within 10 minutes should be detectable by smell. Under such conditions, the chief value of such a test would be to confirm the intake man's suspicions. In the area covered by the A.P.H.A. this confirmation of the intake man's suspicions is more frequently carried out by making a microscopic examination, as the results secured with this technic yield more complete information regarding the past history of the milk.

The Milk and Milk Products Com-

¹ Report of the Standard Methods Committee on Milk and Milk Products. STANDARD METHODS COMMITTEE ON EXAMINATION OF DAIRY PRODUCTS

Organized 1905. Reorganized 1933. Published reports: *Year Books*, 1934-1935, 1935-1936, 1936-1937, 1937-1938, 1938-1939, 1939-1940, 1940-1941, 1941-1942, *A.J.P.H.*, May, 1943. 8 volumes published: 1910, 1916, 1921, 1923, 1929, 1934, 1939, 1941.

HOW TO FIND WHAT HEALTH EDUCATION MATERIALS YOU'RE LOOKING FOR

AT the request of the Managing Editor, the National Publicity Council for Health and Welfare Services, Inc., 130 East 22nd Street, New York 10, N. Y., has prepared an outline that will guide public health

workers, especially those engaged in public health education and in health publicity, to make the best use of available channels of information. Mrs. Beatrice K. Tolleris is the guest editor for this section.

EACH year the National Publicity Council is on the receiving end of hundreds of requests for sources of ready-made health education materials. We are always glad to get them. To our way of thinking, every leaflet, motion picture, radio script or exhibit produced on a health subject is a potential asset to every agency in the field. The wider the knowledge of available material, the less duplication there will be and—even more important—the greater the amount of time, money, and skill freed for other assignments.

This does not mean that other health educators in agencies similar to your own have already turned out exhibits or leaflets which will meet your exact specifications for every conceivable occasion. Rarely will an already finished product be hand tailored to your needs. Very often, however, it will offer you a head start in the shape of valuable suggestions for an adaptation of your own.

Even the materials produced by national agencies for local imprint will probably not fill your total requirements for the year. They may, however, meet a significant proportion of your needs, releasing your time for the production of more specialized materials

designed to fit a particular local situation.

How much use you make of other agencies' material depends upon your ability to find out what is available. How you ask for information is almost as important as whether you ask at all.

Assuming that you have a plan and a thought-out purpose behind your every request for a film, or exhibit, or transcription, you will get much better results if you explain that plan when you make your original request.

It is not enough, for example, to request "a leaflet on rheumatic fever." You may get an excellent pamphlet. But it might be addressed to mothers, explaining home care; it might be an explanation of the reasons behind the doctor's instructions; it might be a general discussion of the prevalence of the disease. And perhaps what you really wanted was an appeal for more hospital beds.

On the basis of our own experience, therefore, we have prepared this brief summary of the kinds of details which any agency would probably need before it could fill your requests satisfactorily.

If You Want a Leaflet

Tell us how you are going to use it. What points should it emphasize—i.e.,

prevention, early diagnosis, treatment or community action? To whom will it be distributed? How many copies will you need? Have you any special requirements as to size, cost, etc.?

If You Want a Radio Program

Do you want a script or a transcription? What are the main points it should cover? Do you want a 5 minute, 15 minute, or ½ hour program? Had you planned for a talk, an interview, a round table, or a dramatization? If you want a dramatic script, will you have the services of a professional cast and director or must it be suitable for amateur production? Will it be part of a series and, if so, what characteristics of other scripts in the series should it match? Are you willing to pay the small fee which some agencies charge for copies of their scripts?

If You Want a Film

Do you want to buy or rent it? When, where, and to whom do you plan to show it? Is your projector 16 or 35 mm., sound or silent? If we cannot find exactly what you are looking for, will you be able to use a film on a related subject and tie it to your theme with a talk? How long a film do you want?

If You Want an Exhibit

What kind of people will see it—i.e., doctors, nurses, industrial workers, school children, or the public at large? Will it be alone or part of an exposition? How much space do you have and what kind of space is it—wall space, table tops, store window? What single message do you want the exhibit to carry? If there is no borrowable exhibit which suits your purpose, have you enough time to build your own on the basis of suggestions we send you? If so, how much money do you have to spend? and can you count on the services of an artist, a photographer or both?

Whatever You Want

Tell us the "who, what, when, where, why" as you would in a newspaper release. Remember that if we are working in the dark we probably will not hit the bull's eye.

Whom to Ask

Naturally you are familiar with the resources of your own city and state health departments and of other local agencies in your community. Frequently, however, state departments and associations other than your own are willing to make their material available to you. On the national level, federal departments, voluntary agencies, and even commercial companies are a fertile source of useful material.

The partial list of national sources which follows is currently up-to-date. We have made no attempt to list specific materials offered by these sources, but in many cases catalogs are available and in most cases the name of the agency will indicate the subject matter and scope of its material.

NATIONAL SOURCES OF MATERIAL

- American Medical Association, 535 North Dearborn Street, Chicago 10, Ill. Films, pamphlets, posters, exhibits, radio scripts, prepared speeches, transcriptions, catalogs, lists.
- American National Red Cross, Washington 13, D. C. Films, pamphlets, posters, exhibits, radio scripts, prepared speeches, transcriptions, catalogs, lists.
- American Social Hygiene Association, 1790 Broadway, New York 19, N. Y. Films, pamphlets, posters, exhibits, prepared speeches, catalogs, lists.
- American Society for the Control of Cancer, 350 Madison Avenue, New York 17, N. Y. Films, pamphlets, posters, exhibits, radio scripts, prepared speeches, transcriptions.
- American Society for the Hard of Hearing, 1537-35th Street, N.W., Washington, D. C. Films, pamphlets, posters, exhibits, radio scripts, prepared speeches, catalogs, lists.
- Maternity Center Association, 654 Madison Avenue, New York 21, N. Y. Pamphlets, posters, exhibits, radio scripts, prepared speeches, catalogs, lists.
- National Committee for Mental Hygiene, 1790 Broadway, New York 19, N. Y. Pamphlets, catalogs, lists.
- National Dental Hygiene Association, 934 Shoreham Building, Washington, D. C. Films, pamphlets, posters, exhibits.
- National Foundation for Infantile Paralysis, 120 Broadway, New York 5, N. Y. Films, pamphlets, catalogs, lists. Posters and exhibits in preparation.
- National Organization for Public Health Nursing,

- 1790 Broadway, New York 19, N. Y. Pamphlets, posters, radio scripts, catalogs, lists. Film in preparation.
- National Safety Council, 20 North Wacker Drive, Chicago 6, Ill. Films, pamphlets, posters, exhibits, radio scripts, prepared speeches, transcriptions, catalogs, lists.
- National Society for the Prevention of Blindness, 1790 Broadway New York 19, N. Y. Films, pamphlets, posters, exhibits, radio scripts, prepared speeches, transcriptions, catalogs, lists.
- National Tuberculosis Association, 1790 Broadway, New York 19, N. Y. Films, pamphlets, posters, exhibits, radio scripts, prepared speeches, transcriptions, catalogs, lists. Address requests to nearest state or local tuberculosis association.
- Planned Parenthood Federation of America, 501 Madison Avenue, New York 22, N. Y. Pamphlets, posters, exhibits, radio scripts, transcriptions, catalogs, lists.
- American Hospital Association, 18 East Division Street, Chicago 10, Ill. One film, pamphlets, radio scripts, prepared speeches.
- U. S. Public Health Service, Washington, D. C. Films, pamphlets, posters, exhibits, radio scripts, prepared speeches, transcriptions, catalogs, lists.
- Children's Bureau, U. S. Department of Labor, 14th and Constitutional Avenue, Washington 25, D. C. Films, pamphlets, posters, exhibits, catalogs, lists.
- Information Division, Women's Bureau, U. S. Department of Labor, Washington, D. C. Films, pamphlets, posters, exhibits, radio scripts, prepared speeches, catalogs, lists.
- John Hancock Mutual Life Insurance Company, Life Conservation Service, 197 Clarendon Street, Boston, Mass. Pamphlets, catalogs, lists.
- Metropolitan Life Insurance Company, 1 Madison Avenue, New York 10, N. Y. Films, pamphlets, window exhibits, prepared speeches, catalogs, lists.
- National Dairy Council, 11 North Canal Street, Chicago 6, Ill. Films, pamphlets, posters, catalogs, lists.
- U. S. Chamber of Commerce, Washington, D. C. Pamphlets, films, exhibits, and posters planned for future production.

Special Sources:

- American Film Center, Section on Health and Medical Films, 45 Rockefeller Plaza, New York 20, N. Y. Descriptive lists of health films with sources, prices, suitability for special audiences and a brief evaluation.
- Johns Hopkins University, Department of Preventive Medicine, 615 North Wolfe Street, Baltimore, Md. Maintains lending library of health exhibits classified under these headings: nutrition, baby care, dental care, diabetes, sanitation, posture, contagion, mental hygiene, industrial hygiene, civilian safety.
- Cleveland Health Museum, 8811 Euclid Avenue, Cleveland, Ohio. Films, slides, posters, exhibits on nutrition, hearing, feeble-mindedness, infantile paralysis, cancer, general health, available on loan.

THE 1944 A.P.H.A. CIRCUIT OF MEETINGS IN THE WESTERN STATES

IT will be recalled that in 1943 a new pattern of meetings in western states was developed under which a team of speakers organized by the American Public Health Association, and with the cooperation of various organizations, made a circuit of 11 state and regional meetings in the West. In response to a demand from a larger number of states in 1944 it was decided to repeat this pattern and to organize a group of specially selected speakers. The officers of the Western Branch, in cooperation with the Executive Secretary of the Association, organized the following team.

- Arthur Massey, C.B.E., M.D., D.P.H., Medical Officer of Health, Coventry, England
- W. Ford Higby, Secretary, Western Branch, A.P.H.A., Secretary California Tuberculosis Association, San Francisco, Calif.
- Chauncey D. Leake, Ph.D., Dean, University of Texas School of Medicine, Galveston, Tex.

- Charles E. Lyght, M.D., Director of Health Education, National Tuberculosis Association, New York, N. Y.
- Martha W. MacDonald, M.D., Psychiatric Services Adviser, U. S. Childrens Bureau, Washington, D. C.
- Karl F. Meyer, M.D., Ph.D., Director, Hooper Institute, University of California, San Francisco
- Ellis S. Tisdale, Sanitary Engineer, U.S.P.H.S., Washington, D. C.
- Pearl McIver, R.N., Principal Public Health Nursing Consultant, U.S.P.H.S., Washington, D. C.
- Henrietta Landau, R.N., Public Health Nursing Consultant, U.S.P.H.S., Denver, Colo.
- William P. Shepard, M.D., San Francisco, Calif.. Metropolitan Life Insurance Company, Pacific Coast
- Reginald M. Atwater, M.D., Executive Secretary, A.P.H.A., New York, N. Y.
- Carl E. Buck, Dr.P.H., Field Director, Committee on Administrative Practice, A.P.H.A., New York, N. Y.
- George T. Palmer, Dr.P.H., Associate Field Director, Committee on Administrative Practice, A.P.H.A., New York, N. Y.

The meetings began in early May with the sessions in Des Moines of the Iowa Public Health Association, following which the team moved to Minneapolis where the State Department of Health had invited the team's participation in the annual conference of official health workers. Then followed the meeting of the Illinois Public Health Association in Chicago, and a meeting in Madison of the public health workers of Wisconsin, where the team of speakers participated on the first day of a three day meeting. Further stops were arranged in Fargo, N. D., in Helena, Mont., where the Montana Public Health Association met, in Spokane, Wash., for the meeting of the Washington Public Health Association, in Moscow, Idaho, for the Idaho Public Health Association, and in Portland, Ore., where a newly organized Oregon Public Health Workers Association had planned a three day meeting.

Extraordinary attendance records were established in these states which made very apparent the enthusiastic welcome extended by the public health workers. They appreciated the fact that national speakers of note were brought near to the front line public health worker himself. In many cases this was the first meeting which some of the nurses, engineers, sanitarians, and the health officers had ever attended where nationally prominent participants were in attendance. The programs were organized on a teaching basis and were of the refresher course variety. Audience participation was cultivated throughout. The final Round Up sessions were lively exchanges between members of the team and members of the audience based on practical questions submitted by those in attendance.

After Portland the team moved to Sacramento for the meeting of the Northern California Public Health Association, and then to Pasadena for the

Southern California group. These California workers attended to the number of about 1,000 for very enthusiastic meetings. The stop in Salt Lake City for the meeting of the Utah Public Health Association was filled particularly full for the team members who appeared three and four times each, and the meeting of the Colorado Public Health Association in Denver was similarly crowded full of lively participation and of dealing with practical problems. The members of the team were regretful that transportation difficulties made it impossible to meet with the New Mexico Public Health Association as planned, but they felt very gratified at the total attendance of more than 5,000 persons in the 13 sessions which were held among the 12 states. Already requests have been received to hold repeat performances in some of these states in 1945, but it is too early to predict whether the Executive Board of the Association will authorize a similar tour next year.

The American Public Health Association and its Western Branch are particularly grateful to the coöperating agencies which made possible the coming of these speakers, including the City Council of Coventry, England, and the British Information Services, the University of Texas, the National Tuberculosis Association, the Children's Bureau, the Hooper Institute of the University of California, the U. S. Public Health Service, the Metropolitan Life Insurance Company, and the many local groups whose coöperation enriched the program.

The central figure of the meetings of 1944 was Dr. Arthur Massey, who was selected to represent his British colleagues by the Ministry of Health of Great Britain. Dr. Massey was a splendid interpreter of current practices in Great Britain, with special reference to the emergency, to health education, and to the British pattern of medical

care as reflected in the White Paper which the British Government has submitted to Parliament.

Dr. Massey, on request, has summarized his impression of the trip as follows:

"My first impression of the United States was the skyline of New York. It exceeded my expectations, although I had expected a lot. I was struck by the geometrical pattern of the streets, for from the ship I could see the whole extent of long parallel thoroughfares. The impression was one of bold architecture and superb town planning. My subsequent few days in New York City confirmed these initial impressions. Naturally, my first reaction was in response to the lights on my first night in New York. It was a thrill to me to see a lighted city after four and a half years of complete blackout.

"I was told that our tour would be a grueling one. But its strenuous nature was more than offset by its congeniality. It is a gamble to bring a party of people together to spend some weeks traveling around as a team; but I was early reassured because there was complete compatibility with and between all members of the party. We were fortunate in that our first meeting at Des Moines was a highly successful one at which we received most cordial treatment at the hands of Dr. Walter Bierring, who is a master in the art of hospitality. Iowa set a high standard which was maintained throughout the tour, and I feel personally indebted to all the responsible officers at each meeting place for their unflinching courtesies and unremitting help.

"A first visit to a great country like the United States is a memorable experience, especially in view of the wide geographical variations state by state which give one a constantly changing chain of impressions. The latter tend to divide themselves into compartments

according to geography. In the Middle West I saw two extremes, from the immensity and sophistication of Chicago to the sparseness and romance of the ranch lands of North Dakota and Montana. In between were the rich agricultural terrains of Minnesota and Wisconsin. Then I have vivid impressions of the Columbia River Country, joining Washington State, Idaho, and Oregon. California I place in a category alone and the word will always conjure up in my mind a picture of the blue Pacific Coast, sub-tropical fruits, redwood trees, and film stars. All these I saw during my visit and I was nowhere disappointed. I especially recall a certain *recherché* luncheon in San Francisco given in my honor by Dr. Karl Meyer.

"Having crossed the arid Mojave Desert, I felt the great contrast between it and the freshness and hospitality of Salt Lake City. The final call at Denver I associate with the scenic Rocky Mountains of Colorado and with a motor trip to the heights and with an excellent weekend's trout fishing. A certain club dinner given by Dr. Fred Foard is one of many happy landmarks.

"I am not sure that I ought to have mentioned any specific occasions of the tour because all the trip was similarly enjoyable. It was due to the generosity of the organizing officers at each stop and to the congenial company provided by members of the team. All of these it is my privilege to regard as permanent friends. I can only hope that if a team is formed for a tour next year they will be as thoroughly happy together as we have been this year.

"I feel that the members of the team were most amused at my obvious enjoyment of vanilla ice cream twice daily and of my breakfast of bacon and two eggs each morning. These are great treats to one from Great Britain nowadays!

"At the end of the tour I was convinced that the team had done a considerable service at the various state

health meetings by imparting up-to-date knowledge, and above all by submitting eagerly to the barrage of questions which everywhere characterized the 'round up' sessions. At every meeting we taught and learned.

"I am looking forward to telling Sir Wilson Jameson (Chief Medical Officer, Ministry of Health, England) of the excellent experiences I have had, and

of thanking him and also the Coventry City Council for the opportunity they gave me for visiting a great and progressive country.

"My final word is one of very cordial thanks to the American Public Health Association and to the Secretary, Dr. Atwater, for making these arrangements possible and for their wonderful treatment of their guest from England."

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted.

Clinical Tropical Medicine—*Edited by Z. Taylor Bercovitz. New York: Hoeber, 1944. 957 pp. Price, \$14.00.*

This new textbook of tropical medicine has been prepared with the cooperation of twenty-seven contributors, including the editor. In this method of preparation the book differs from the other recent textbooks of tropical medicine in the English language. The contributors are all among the best authorities in their respective fields, and some of the sections are the best that the reviewer has seen in textbook form. Each contributor has apparently been given a wide latitude in presentation, although each disease is considered under the usual textbook headings.

Among the most valuable sections are those on the diseases caused by Rickettsiae by Henry Pinkerton, those covering pinta and yaws by Howard Fox, yellow fever by Fred L. Soper, psittacosis by K. F. Meyer, tularemia by Lee Foshay, undulant fever by A. V. Hardy, leprosy by George W. McCoy, nutritional diseases by Edward B. Vedder, and mycotic diseases by Morris Moore. A few of the sections are rather superficial in presentation and are poorly organized, such as the section on diarrheal diseases, where some of the intestinal protozoa are presented in more than one place, and the classification of all of the intestinal flagellates is given under giardiasis after the individual members of the group have been presented in the previous chapter. In the chapter on bacillary dysentery, the bacteriology of the disease has received insufficient attention and, under treatment, polyvalent anti-serum is given a prominent place without reference to type of organism involved.

The chapter on arthropods is limited to those injuring man and does not relate them sufficiently to the transmission of diseases. Unfortunately, this section was not prepared by a medical entomologist.

The illustrations are numerous and excellent. Many of them have been borrowed from other standard works, such as Dobell's *Monograph on the Intestinal Protozoa* and Wenyon's *Protozoology*. Many others are original, those in the section on mycoses being particularly good. The book is published in excellent style and is unusually free from typographical errors. One only wishes that such textbooks could be printed on paper which would make the volume easier to handle. It will prove to be a valuable reference book for medical students, instructors, public health departments, and physicians who are interested in tropical medicine, but it should be supplemented by other modern textbooks.

HENRY E. MELENEY

The Youngest of the Family—His Care and Training—*By Joseph Garland, M.D. (rev. ed.). Cambridge, Mass.: Harvard University Press, 1943. 182 pp. Price, \$2.00.*

This is a new edition of another of the many books written to help mothers raise babies. It contains a good discussion of the variations in growth and development commonly observed in children, and calls for a common sense attitude toward clothing. In general, the approach is one of tolerance and understanding, but there will be considerable disagreement with the author's advice on very early toilet training.

Insistence on breast milk for prema-

ture infants seems hardly justified when there is so much evidence that other milks may be at least as satisfactory.

MYRON E. WEGMAN

Pathology and Therapy of Rheumatic Fever—By *Leopold Lichtwitz*. New York: Grune & Stratton, 1944. 198 pp. Price, \$4.75.

Dr. Lichtwitz's book is based on the thesis that rheumatic fever is an allergic disease. In order to develop this theory, experimentally proven facts are intermixed with clinical impressions and rules of thumb. The discussion of the relationship of the central nervous system to the allergic theory of acute rheumatic fever is particularly obscure. Although this theory may finally prove to be correct, the case for it has not been clearly made in this volume.

The text of the book is not limited to rheumatic fever but to rheumatic manifestations of many diseases. There is a constant intermingling of statistics and facts relating to various types of rheumatic disease so that, even for one somewhat familiar with the literature, it is difficult to follow the argument. For those interested in theorizing discussions of rheumatic fever, the reading of the early chapters of this book may provide the framework on which experimental studies may be designed. It is of interest that in this book on rheumatic fever, even in the discussion of prognosis, the words "sub-acute bacterial endocarditis" never appear. This book is definitely not designed for the general practitioner.

The charming foreword by William J. Maloney makes excellent reading.

DAVID D. RUTSTEIN

War and Children — By *Anna Freud and Dorothy T. Burlingham*. New York: International University Press, 1943. 191 pp. Price, \$2.00.

This small book was written primarily for American parents but it has a

message for a much wider audience, among parents of all countries as well as professional workers in public health, medicine, education, and psychology. The authors are pioneers in nursery school work, Anna Freud being the daughter of Sigmund Freud who introduced psychoanalysis, while Dorothy T. Burlingham is an American psychologist. Both have long been interested in the psychological development of children and have fostered the development of facilities wherein are provided proper emotional relationships for the child.

The war brought the authors to England where they established three nursery schools which differ greatly from the customary peacetime nursery schools or day nurseries of the Continent and the United States, and which resemble more a kind of foster home.

The book is written simply and clearly, and has excellent illustrations. It is divided into two main divisions; part one deals with such things as the psychological reactions of the child to destruction, air raids, evacuations, and separation from parents, and formulates practical methods of dealing with the behavior set-off by these traumatic influences; part two is made up of reports and case records of individual children and gives in detail the reactions which are discussed more generally in the preceding part; there is included an outline, with some discussion, of the training courses for young women who work in the nurseries.

The book not only provides facts which are of interest in terms of psychological reactions of children to unusual trauma but points out clearly the relationship between emotional maladjustment and the home life in the first five years of life. This book then becomes a primer of child care in peacetime as well as a record of the disastrous influence of war.

MILTON J. E. SENN

A Survey of Alcohol Education in Elementary and High Schools in the United States—By *Anne Roe, Ph.D.* *New Haven, Conn.: Quarterly Journal of Studies on Alcohol, 1943.* 132 pp. Price, \$1.00.

For a long time many of us have suspected that something was definitely wrong with teaching practices and teaching materials in alcohol education. Fortunately Dr. Roe has performed a most successful "exploratory operation" on the "subject" of alcohol education as it is now presented through the medium of health education textbooks prepared especially for use by children and by adolescents in public, private and parochial schools throughout the United States. One hundred and sixty-six books and publications, including 137 textbooks, were explored. Current teaching practices and teaching materials are tabulated systematically, and are discussed critically from the standpoint of scientific validity and pedagogic caliber.

Dr. Roe's "operative" findings disclose that a considerable portion of the material about alcohol knowledge in these textbooks is scientifically invalid. Many of the writers display a tendency to vagueness of terms, and indiscriminate generalizations. These same authors frequently present material without foundation of scientific fact, especially when speaking of alcohol as a habit-forming drug, a poison or narcotic, when describing the effects of alcohol on nutrition, on resistance to disease, on heredity and longevity, and when including statistics concerning alcohol as a direct or contributory cause of disease. One of the chief faults to be found with discussions on alcohol as a poison or narcotic, is the complete disregard in nearly all of the textbooks of the distinction between the effects of drinking small amounts of alcohol and of excessive drinking. Authors rarely keep this distinction clear.

Instead, they seek to espouse the cause of total abstinence rather than to present the known facts about alcohol and its effects.

The latter half of the book deals with the legal regulations of alcohol education and analyzes those laws of the states which make mandatory the inclusion of alcohol education in the school curricula. There is an excellent list of standard references, an exhaustive bibliography of textbooks which the author reviewed in her searching analysis of alcohol education, and a bibliography of state laws on alcohol education. Members of committees on health education textbooks and authors of such books will find it to their advantage to read this volume.

I. H. GOLDBERGER

Manual of Industrial Nutrition. 25 pp.

Planning Meals for Industrial Workers. 28 pp.—By *Food Distribution Administration, Nutrition and Food Conservation Branch, U. S. Department of Agriculture.* *Washington, D. C.: U. S. Govt. Ptg. Off., 1943.*

The Food Distribution Administration of the U. S. Department of Agriculture has issued these two pamphlets as the first of a series designed to aid in the program of raising the nutritional status of the vast numbers of workers engaged in American industry. In the preparation of these brief manuals the Nutrition in Industry Division of the Nutrition and Food Conservation Branch has rendered a valuable service by concisely presenting how any industrial plant or community may undertake the protection or obtain advice on how to protect the health of industrial workers through good nutrition.

The *Manual of Industrial Nutrition* provides an excellent outline of the job to be done and the technics which are proving successful in meeting a long-

time need greatly aggravated by wartime industrial conditions. It is worthy of comment that attention is given not only to what can be accomplished by a sound nutrition program but also to factual refutation of some of the claims that a single or multivitamin preparation will provide an answer to all industrial medical problems.

The second pamphlet, *Planning Meals for Industrial Workers*, should prove useful to those responsible for the actual planning and supervision of meals. THOMAS D. DUBLIN

Physical Fitness Through Health Education for the Victory Corps, 1943. 98 pp. Price, \$.20.

Handbook on Physical Fitness: For Students in Colleges and Universities, 1943. 140 pp. Price, \$.25—*Prepared by a committee appointed by the U. S. Commissioner of Education with the collaboration of the U. S. Army, the U. S. Navy, the U. S. Public Health Service, and the Physical Fitness Division of Defense Health and Welfare Services. Washington: Supt. of Documents, U. S. Govt. Ptg. Off.*

These manuals are approved by the representatives of the Army, Navy, U. S. Public Health Service, and U. S. Office of Education. Representative and well qualified persons, including teachers of physical education, health education experts, medical and other specialists, served as special committees to prepare the manuals.

There can be no doubt that physical education and health education in secondary schools, colleges and universities have been advanced greatly during the war, and that the initial stimulus came from manuals such as these, developed by the various departments of the federal government. The urgency of the war effort has broken down departmental lines. Physical fitness is being stressed even at the expense of other studies and practices.

Directors, principals, classroom teachers, physical education teachers, school physicians, and nurses, health department health services, and numerous voluntary agencies, are now working together as never before in the efforts to find physical and dental defects and have them corrected, to prevent and control communicable diseases, improve nutrition, physical fitness and endurance.

These manuals suggest methods and technics for action as well as giving specific advice and information.

The first manual, *Physical Fitness Through Health Education for the Victory Corps* provides six objectives as a basis for a wartime emergency program on health education in high schools. These include: (1) correction of remediable defects; (2) prevention and control of communicable diseases; (3) improvement in nutrition; (4) prevention of accidents and training to assist in giving emergency care; (5) daily program planning for balanced living; and (6) development of sound mental attitudes.

The *Handbook on Physical Fitness for Students in Colleges and Universities* seems also to have met a decided need. From physical education experts with whom the reviewer consulted, he learns that for men, the manual contains excellent material which can be elaborated and expanded according to facilities available. It provides a well rounded program and counteracts the over-stressing of intramural and intercollegiate sports. For women, the all-round program suggested has been received as sound and useful. The chief complaint seems to be that in many colleges and universities, the time and the personnel available are insufficient adequately to carry out the suggested program.

John W. Studebaker, U. S. Commissioner of Education, states:

In light of contemporary developments, it

has become increasingly apparent that our colleges and universities can perform no greater service at this time than to provide programs and facilities through which their students may become physically fit. Physical fitness may mean the difference between life and death for men entering the armed forces. Physical fitness is also of utmost importance to men and women who participate in industrial and agricultural programs.

This manual points out with authoritative information how to reach the above ends. CARL A. WILZBACH

A Hundred Years of Medicine—
By C. D. Haagensen and Wyndham E. B. Lloyd. New York: Sheridan House, 1943. 444 pp. Price, \$3.75.

This American edition of a series of essays on the history of modern medicine (which has also appeared in an English edition) is another of the many attempts in recent years to popularize the subject. This one has some advantages for the public health worker, for it touches on subjects of interest to him which many others do not, as, for example, the sanitary conditions and the state of hospitals in the 1800's, as well as the social aspects of medicine as seen today. But, in general, the story is that of the developments of chemotherapy and anesthesia, the conquest of various diseases, the rise of certain specialties (neurosurgery, orthopedics), the use of radium and vitamins, etc. The authors have done well in tracing chronologically the development of their separate topics. The story is told, however, in a style that left this reader less than convinced that it would satisfy either the layman or the expert. The confusion seems due to a mixture of technical and everyday language and to the hodge podge of biographical anecdote and anatomic, bacteriologic, or clinical background which adorn the tale. In view of the many new subjects discussed, it is surprising that those of air sterilization

and the relationship of jungle fever to yellow fever control were omitted. Despite these shortcomings, the volume does contain a substantial amount of accurate information on the developments in medicine in the past one hundred years.

LEONA BAUMGARTNER

Nutrition Reviews. Vol. 1, Nos. 1-14. November, 1942-December, 1943. New York: Nutrition Foundation, 1944. 443 pp. Price, \$2.00, Domestic subscription; \$2.50, Foreign.

If any further proof of the tremendous expansion of the field of nutrition were needed, it might be found in these more than 400 pages of abstracts covering 14 issues of this monthly publication of the Nutrition Foundation, New York, N. Y. A critical review of the contents would be as difficult as reviewing the encyclopedia. One must recognize, however, the competence of the staff of reviewers and be grateful for this public service of the Nutrition Foundation. For succinct and yet comprehensive presentation of the literature, this volume has few equals.

REGINALD M. ATWATER

Physical Fitness for Girls: Contributions of Physical Education to War-Peace Programs in Secondary Schools—By Rosalind Cassidy, Ed.D., and Hilda Clute Kozman, Ph.D. New York: Barnes, 1943. 223 pp. Price, \$2.00.

Fitness First: A Physical Fitness Workbook for High School Girls—By Hilda Clute Kozman and Rosalind Cassidy. New York: Barnes, 1943. 32 pp. Price, \$.60.

These books have been written to enable schools to meet the immediate wartime demands on secondary instruction, but present a program so practical and a philosophy so appealing that their usefulness will extend far beyond

the "duration" into the years when peace and security are once more taken for granted by education. The textbook is designed specifically for college students who are preparing to be teachers of girls in the high school physical education program. This is not, however, an inclusive text; its "materials and methods are delimited to those thought suitable for building understandings and skills in endurance, strength, body control, relaxation and morale in an orientation course" (p. 45). The authors state plainly that they do not advocate discarding the valuable program already established in girls' physical education, even though they make no attempt to describe this in detail. It is important for the reader to have this limitation clearly in mind; otherwise the plan presented will seem narrow and somewhat poverty-stricken, in comparison to the wealth of activities, goals, and materials characteristic of modern physical education.

To "redirect emphasis to elements of physical fitness that have always been important for the physical education teacher," the authors suggest an orientation course, given first for all girls in the school, later for new girls and for those who can profit by its repetition. The assumption is that graduates from the orientation program will go on to such activities as sports, dancing, etc., now characteristic of secondary school offerings. The book offers a way of meeting the urgent wartime demand for revising present-day programs, without returning to gymnastic regimentation and autocratic response-command systems. "The disciplines of democracy are self-discipline, self-control and self-direction . . . in coöperation with others for the common good" (p. 40). In a time when there is thoughtless acceptance of "commando" training as proper activity for young girls in school

and college, it is more important than generally realized to have such a book as this, which Lindeman in his Preface felicitously describes as "both an antidote for the wrong type of physical education for young girls and a straightforward, usable plan for something better" (p. V).

School health officers, both physicians and nurses, will find encouragement and appreciation of their services in this teacher training text; and they will not find themselves embarrassed by careless statements or naïve enthusiasms. Experience, reflection, wisdom, as well as specialized knowledge and competence, have gone into the making of these books.

EDNA W. BAILEY

Manual for Water Works Operators—By the Texas Water Works Short School. (rev. ed.) Austin: Texas Water Works Short School, 1943. 392 pp. Price, \$3.00.

This represents a condensed reference work on the operation of public water supply systems. It is a useful volume for all local water supply officials, although intended primarily for those of Texas. The revised edition adds 106 pages and new features to the first edition of 1938. The Drinking Water Standards of the U. S. Public Health Service and the associated manual are reprinted as an appendix.

Twenty-three authors have contributed a series of chapters upon sources and protection of water supply, pumping, metering, treatment (7 chapters), distribution system maintenance, storage, industrial water supplies and the requirements of several Texas State Departments pertaining to water supplies. Several appendices and a comprehensive index complete the volume.

Within the scope of a condensed reference work much information is given as to all aspects of the opera-

tion of public water supplies. The volume will be of chief value to those desiring a fundamental knowledge as to the general field of operation rather than to specialists interested in the restricted aspects of water supply or water purification plant operation.

As might be expected with a text prepared by so many authors, there is a certain lack of functional coördination in the discussion of several aspects of water quality and the related processes of water treatment. Thus one finds disconnected portions of the text dealing with different aspects of the same general subject, such as water chlorination. Occasionally the text overemphasizes certain technical details at the expense of operating details. For instance, Chapter XII entitled "Algae and Water Supplies" presents in a useful form the biology of aquatic vegetation, but contains only one short paragraph on methods of application of copper sulfate for algae control, and no mention is made as to the practical aspects of collecting representative samples for microscopical examination to enable control procedures to be intelligently utilized.

In a similar way the discussion of the chlorination of water makes no mention of the effects of water temperature, pH, available period of contact before the treated water is delivered to the first consumer, nor of the practical use of the orthotolidine test in compensating for such influences. Furthermore, no mention is made in the directions for the orthotolidine test of errors due to nitrate, manganese, color, turbidity, etc.

The chapter on bacteriological examination of water represents a popular review of the standard laboratory procedures but presents no background as to general water bacteriology nor as to the interpretation of the results of the examinations in terms of purification plant and water supply control.

Notwithstanding these and similar deficiencies, the revised edition of this book represents a convenient reference work as to all aspects of public water supply operation which should be of greatest assistance to those desiring general information upon those aspects of water supply operation which are foreign to their experience.

C. R. Cox

Red Cross Home Nursing—By Lona L. Trott, R.N. B.S., School Edition edited by Gertrude E. Cromwell, R.N., M.S. Illus. Philadelphia: Blakiston, 1943. 363 pp. Price, \$1.00, cloth, \$.60 paper.

This book has been especially prepared for use with senior high school students. Much of the material was adapted from the former *American Red Cross Textbook on Home Nursing*. New and revised material on general health is included in the chapters (Section 1) on "Personal Readiness to Meet Everyday Problems." The presentation of the subject matter in the other three sections *i.e.*, When Sickness Invades the Home, Understanding Child Growth and Development, and Protecting the Health of Our Homes and Community, should appeal to 11th and 12th grade students.

The presentation in Section 1 may be found too elementary for the present-day high school age group.

Drawings and photographs are effectively used to illustrate many of the simple nursing technics.

Teachers of Red Cross home nursing courses in high school should welcome this long overdue textbook.

LULU ST. CLAIR BLAINE

Handbook for Use of Instructors and Administrators — *Red Cross Home Nursing, School Edition, American Red Cross, Washington, D. C.*, June, 1943. 54 pp.

The new and the experienced teacher

should find this handbook useful in planning for and carrying out a home nursing instruction program in senior high schools. It was designed to be used in conjunction with the textbook *Red Cross Home Nursing*. How to organize classes and to fit the course into the school program is outlined. Materials needed for the course are listed. Suggestions for use of the materials are offered, as well as a reading list for the instructor. This handbook should be indispensable to any instructor of home nursing.

LULU ST. CLAIR BLAINE

Handbook for the Etiology, Diagnosis and Control of Infectious Bovine Mastitis—By Ival Arthur Merchand and R. Allen Packer. Minneapolis: Burgess Publishing Co., 1943. 66 pp. Price, \$1.25.

This handbook has been prepared for students from lecture notes and field experience. It is also valuable for the practising veterinarian as it contains concentrated, up-to-date information concerning this important disease. Various chapters discuss the predisposing factors, the bacteriology of mastitis, and the diagnosis, control, and treatment of the disease. The disappointing feature of this summary, as must be the case with all summaries of our present knowledge, is that no adequate cure, control, or eradication program can be presented for this wasteful scourge.

ROBERT S. BREED

Brucellosis in Man and Animals—By I. Forest Huddleson. (rev. ed.). New York: Commonwealth, 1943. 379 pp. Price, \$3.50.

Economically, and considering occurrence and duration of infection, Brucellosis now assumes first place among diseases transmissible from animals to man. It is fitting and fortunate that this book should have as its author a

veterinarian, an investigator recognized internationally as an authority on this subject.

Seven Chapters are arranged as follows: I—The Genus *Brucella*, II—Methods of Isolating *Brucella*, III—Differentiation of the Species of the Genus *Brucella*, IV—Brucellosis in Human Beings, V—Brucellosis in Animals, VI—Laboratory Diagnosis of Brucellosis, and VII—Eradication or Control of Sources of *Brucella* Infection.

In Chapter IV, Part Two, "Brucellosis in the United States," was contributed by A. V. Hardy, M.D., Consultant U. S. Public Health Service, and Part Three, "Brucellosis in Malta," by J. E. Debono, M.D., of the Royal University of Malta. Chapter VII and the Preface were written by Ward Giltner, D.V.M., Dean of the Veterinary Division of Michigan State College.

This book embodies a wealth of information pertaining to symptomatology, diagnosis, and methods of treatment (sulfatherapy, brucellin, artificial fever therapy), and will prove a valuable guide to physicians. The volume is essential to bacteriologists and laboratory workers, whose interest is the study of brucella, its isolation, species differentiation, and laboratory diagnosis. Veterinarians, livestock sanitarians, and public health administrators will learn much from this book about Brucellosis in animals, including the present status of calfhood vaccination with strain No. 19.

The treatise incorporates an appendix of case reports, a bibliography with 485 references, significant historical high lights, and a stimulus which will lead to further knowledge, more effective control, and prevention of an important but partly known communicable disease.

CARL F. JORDAN

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Outspoken Reporting — Gordon Bates tells of an increase in syphilis in his city, and, what is more disturbing, an increase in recently acquired syphilis. He found this out by asking the doctors, as he does from time to time.

BATES, G., A Survey of the Incidence of Venereal Diseases in Toronto in 1943. *Canad. Pub. Health J.* 35, 6:234 (June), 1944.

Where Polio Struck—If in nothing else, you will be interested in the map showing the nation-wide distribution of poliomyelitis in 1943. In the discussion of the behavior of this disease, it is pointed out that neither differences in climate, geography, density of population, nor racial characteristics seem to be factors of importance in accounting for variations in numbers of outbreaks.

DAUER, C. C. Prevalence of Poliomyelitis in the United States in 1943. *Pub. Health Rep.* 59, 22:712 (June 2), 1944.

Rheumatic Fever in England—“Rheumatism may lick the joints, especially in childhood, but it bites the heart.” Nice aphorism, isn’t it? The paper, otherwise, is good, too.

DONOVAN, G. E. Some Aspects of Cardiovascular Disease With Special Reference to Public Health. *Pub. Health.* 57, 8:85 (May), 1944.

Good Works — Wholesomely frank is this review of how little we really know about poliomyelitis. The activities of the National Foundation in supporting research, training physicians, nurses and technicians—1,300 since 1942—and disseminating information are recounted with a pleasing absence of self-administered back-patting.

FISCHOFF, E., and GUDAKUNST, D. W. The Fight against Infantile Paralysis Continues. *Am. J. Nurs.* 44, 6:533 (June), 1944.

The Professors Look at Kenny—After pulling the wobblies of the props out from under some of Sister Kenny’s overenthusiastic claims for her method, this committee admits, a little grudgingly, that her contentiousness “has stimulated the medical profession to reëvaluate known methods of treatment.” For that understatement the eminent professors should be awarded the big brown derby!

GHORMLEY, R. K., *et al.* Evaluation of the Kenny Treatment of Infantile Paralysis. Report of Committee. *J.A.M.A.* 125, 7:466 (June 17), 1944.

Papers-of-the-Month — Whether you sit behind an executive’s desk, or before a laboratory table, or visit homes, or inspect food handling establishments, you should read this symposium on “The Treatment of Burns.” As one of the writers says “much controversial matter appears to have been settled,” and you owe it to yourself to be informed about the settlement. So you’ll find no superficial abstracting done here. There will be seven papers in all: read all seven.

HARKINS, H. N. The Problem of Thermal Burns (and six related papers). *J.A.M.A.* 125, 8:533 (June 24), 1944.

For Venereal Patients Who Can Pay—Every health administrator will be interested in this straightforward account of an effort to increase the proportion of venereal patients treated by practising physicians in Philadelphia. The program did materially improve the previously tragic picture and the method might find applications in the epidemiology of other diseases.

INGRAHAM, N. R., and GREENBAUM, S. S. Public Health Venereal Disease Control. *J.A.M.A.* 125, 8:527 (June 24), 1944.

For Your Soul's Good—Unless we who work in health . . . are ourselves free from prejudice and intolerance, we cannot hope to work with full effectiveness, says this fellow, who takes intolerance apart to see "what makes it tick."

KILPATRICK, W. H. *Applied Democracy in Inter-Group Relationships*. Pub. Health Nurs. 36. 6:265 (June), 1944.

"Who Owns Health?"—We learn from the President of the A.M.A. that venereal diseases are almost completely controlled; that pneumonia is no longer a danger; that cerebrospinal meningitis mortality is now about 5 per cent; that the local medical profession will readily take care of whatever pellagra is found; that as a result of the wonderful achievements of medicine the life span has increased from 40 to 65 years; that army doctors wonder what they are fighting for; that under our present system of medical practice the people of this country have enjoyed the best health record of any nation on earth.

KRETSCHMER, H. L. *American Medicine and the War*. J.A.M.A. 125, 7:461 (June 17), 1944.

Next-Steps-in-Science Department—It seems that when suspensions of bacteria or viruses are allowed to flow in a ribbon-like stream past a new type of ultra-violet lamp they are rapidly inactivated, and with a minimum loss of antigenicity. This paper tells about the results of such treatment on colon, typhoid, and certain salmonella, streptococcus and pneumococcus cultures. Rabies and encephalitis vaccines treated in this way induced a high degree of immunity in mice.

LEVINSON, S. O., *et al.* *Production of Potent Inactivated Vaccines with Ultra-violet Irradiation*. J.A.M.A. 125, 8:531 (June 24), 1944.

Medical Care for All Canadians—That all the known health measures conducive to the prevention and control of illness should be made available to all people is axiomatic, says the Minister of Pensions and National Health. The solution of the problem of the provision of adequate medical care lies in health insurance, he adds. Rugged individualists hereabouts will disagree with his extension of these introductory remarks.

MACKENZIE, I. A. *Health Insurance*. Canad. Pub. Health J. 35. 6:213 (June), 1944.

About Beautiful Ideas That Turn Sour—A successful boomerang is something you throw into the air and which hits you in the back of the neck if you don't watch out. As a great many health publicity ventures seem to turn into that kind of boomerang, every administrator with a yen for health education, will profit by reading this excellent dissertation. Incidentally, this is but one among many such stimulating papers that have appeared recently in *Channels* only to be ignored in this bibliography. To the able editors of *Channels* go my abject apologies for this neglect.

MERTON, R. K., and KENDALL, P. L. *The Boomerang Response*. Channels. 21, 7:1 (June). 1944.

"Telling All" to High Schoolers—Reporting upon a two year experience with the group-discussion method of venereal disease education (for high school youngsters) in which men and women speakers furnished by the divisional health department lead the discussions. Integration of social hygiene in the science units may be a preferred method, but this one works too, is the claim of these Canadian writers.

RHODES, H. C., and CAPELLE, P. M. C. *Venereal-Disease Education in the High School*. Canad. Pub. Health J. 35, 5:181 (May), 1944.

Despite Ecclesiastes 1:8—Not to be confused with infections mononucleosis, is still a newer disease—acute infectious lymphocytosis—which threatens to add to the epidemiological troubles of the public health fraternity. As it is a communicable condition, with upper respiratory symptoms most frequently featured, epidemiologists had better acquaint themselves with the differential diagnosis discussed in this paper. Still another virus is suspected.

SMITH, C. H. Acute Infectious Lymphocytosis: A Specific Infection. *J.A.M.A.* 125, 5:342 (June 3), 1944.

Moses Was a Shrewd One—Exposure to trichinosis infestation is nearly uniform regardless of geographical or environmental factors. Evidence in hand points to the need for nation-wide preventive action.

WRIGHT, W. H., and WALTON, A. C. Studies in Trichinosis. *Pub. Health Rep.* 59, 21:669 (May 26), 1944.

NOMINATIONS FOR THE GOVERNING COUNCIL

In accordance with the By-laws of the Association, the Nominating Committee for Governing Council Members consisting of one Fellow from each Section, reports the following nominations for the Governing Council. The By-laws provide that "upon the petition of twenty-five Fellows, the Nominating Committee shall add the name of any Fellow to this list, provided such petition is received fifteen days before the Annual Meeting." The Chairman of the committee is J. J. Bloomfield, Industrial Hygiene Division, U. S. Public Health Service, Bethesda, Md. The other members are: Jessie M. Bierman, M.D., School Health Section; Martha L. Clifford, M.D., Maternal and Child Health Section; Arthur H. Graham, M.D., Epidemiology Section; Leonard Greenburg, M.D., Industrial Hygiene Section; Albert C. Hunter,

Ph.D., Food and Nutrition Section; Hugh R. Leavell, M.D., Public Health Education Section; Roy J. Morton, Engineering Section; Hugo Muench, M.D.,* Vital Statistics Section; Sophie C. Nelson, R.N., Public Health Nursing Section; George A. Nevitt, D.D.S., Dental Health Section; William D. Stovall, M.D., Laboratory Section; George M. Uhl, M.D., Health Officers Section.

There are thirty elective councilors on the Governing Council, of whom ten are elected each year. The ten Fellows receiving the highest number of votes on a written ballot cast by the Fellows present and voting at the Annual Meeting in New York City will be elected for the three year term 1944-1947.

* Alfred J. Lotka, D.Sc., acted as alternate for Dr. Muench when the latter became ill.

Salary available to start \$2,400 per annum increasing to \$2,700 for satisfactory service. Assistant bacteriologist also needed, with available salary of \$1,800 increasing to \$2,000 if satisfactory service is shown. Write Box N, Employment Service, A.P.H.A.

Wanted: School dentist to direct and operate school dental program in southeastern city of 70,000 population. Salary available starting at \$3,600 and increasing to \$4,000 for satisfactory service. For further particulars write Box Y, Employment Service, A.P.H.A.

Wanted: An assistant in Health Division Council of Social Agencies, interested in community organization and health education. Large city and metropolitan area. State age, training and experience. Write Box X, Employment Service, A.P.H.A.

FOR OTHER POSITIONS AVAILABLE WRITE EMPLOYMENT SERVICE, AMERICAN PUBLIC HEALTH ASSOCIATION, 1790 BROADWAY, NEW YORK 19, N. Y.

In view of the current active demand for trained and experienced persons in public health, it is suggested that prospective employers communicate directly with the Employment Service, American Public Health Association, 1790 Broadway, New York 19, N. Y., for up-to-date lists of applicants.

POSITIONS WANTED

ENGINEER

Well qualified public health engineer seeks responsible position in New York metropolitan area. E-480

Sanitary Engineer, C.E. 22 years' experience as sanitary engineer, 14 as director in state health department, now employed. Desires change. Location immaterial. E-481

LABORATORY

Research bacteriologist - veterinarian, now in civil service, desires change to direct or indirect war work. P-3 classification. Considerable laboratory and field experience. Used to foreign travel; will go anywhere. Steady hard worker. L-470

Bacteriologist, 29, draft exempt, 3 years' experience public health laboratory, 2 years' experience industrial organization. Experienced in investigation and

control activities on water, sewage, and sanitation as chemist, bacteriologist and serologist in syphilis and enteric diseases. L-465

Bacteriologist-Serologist, male, with 20 years' experience in state and municipal public health laboratories, last 10 years in administrative capacity, now in charge of a midwest diagnostic laboratory, wishes to make a permanent change. L-427

MISCELLANEOUS

Public Health Nurse. B.S. in nursing. William and Mary College, age 53, seeks position as coördinator of public health nursing, educational director, or director student nurse public health program. Prefers Middle Atlantic States. M-452

Sanitarian-Veterinarian, age 23, seeks employment in public health field. Experienced as veterinarian, serologist, sanitary inspection. M-460

NEWS FROM THE FIELD

PENICILLIN AND SYPHILIS

According to the *Venereal Disease War Letter* issued by the U. S. Public Health Service, Division of Venereal Diseases, Washington, D. C., in co-operation with state health departments, large-scale use of penicillin in the treatment of syphilis is being undertaken by the U. S. Public Health Service and a number of state health departments. J. R. Heller, Jr., Medical Director and Chief of the Venereal Disease Division of the Service, has indicated that several hundred patients with syphilis will be treated with penicillin at rapid treatment centers within a year under this program.

According to Dr. Heller, in several centers studies of the effectiveness of penicillin in the treatment of syphilis will be conducted in collaboration with the Penicillin Panel, Subcommittee on Venereal Diseases of the National Research Council. The data from selected cases will make possible further evaluation of different time-dosage schedules, the most effective of which have not as yet been fully established. Evidence of the value of penicillin in the treatment of syphilis, on the other hand, is already sufficient to warrant large-scale application of the therapy in the interest of both public health and the prospects for recovery of patients for whom the treatment is appropriate.

Three patients treated for early syphilis by U. S. Public Health Service physicians at the U. S. Marine Hospital, Staten Island, N. Y., in 1943 (*A.J.P.H.*, Dec., 1943) remain free of clinical or serologic evidence of syphilis as the period of post-treatment observation approaches a year.

Since the Staten Island research,

additional studies have been conducted by the Army, the Navy, and the U. S. Public Health Service in collaboration with the Penicillin Panel. More than 1,000 patients with syphilis in various stages have been treated with penicillin. Accumulating evidence indicates that penicillin does have value in the treatment of syphilis of all types, although additional time must pass before permanence of results can be judged. In many of the cases treated primary and secondary lesions have healed quite promptly. *Treponema pallidum* as observed by darkfield examinations have disappeared in 12 to 24 hours, and blood serologic tests have reversed from positive to negative.

The use of penicillin in this program will be restricted to patients with untreated, early syphilis, darkfield positive, and patients for whom 6 months' or a year's follow-up seems possible. Two schedules of therapy are being considered in the U. S. Public Health Service program—a 4 day schedule and an 8 day schedule.

The first group of State Rapid Treatment Centers, operating in co-operation with the U. S. Public Health Service physicians assigned to state health departments, which will participate are at San Diego, Calif.; Denver and Pueblo, Colo.; Ocala, Wakulla, and Jacksonville, Fla.; Pineville and New Orleans, La.; Ann Arbor, Mich.; Meridian and McLain, Miss.; Albuquerque, N. M.; Charlotte, N. C.; Rush Springs, Okla.; Columbia, S. C. (3 centers); Nashville, Chattanooga, and Memphis, Tenn.; San Antonio, El Paso, and Waco, Tex.; Richmond, Va.; Seattle and Grand Mound, Wash.; and Washington, D. C. Federal Rapid Treatment Centers participating are at

Birmingham, Ala.; Hot Springs, Ark.; Pensacola, Fla.; Savannah and Augusta, Ga.; Greenwood, Miss.; St. Louis, Mo.; Durham, N. C.; Norfolk, Va.; and Charleston, W. Va.

Clinics and physicians are urged to refer suitable patients to nearby RTC's.

RED CROSS TO SUPPLY MEASLES GLOBULIN

The American Red Cross has announced its expectation that by September 1 measles globulin prepared from blood donated by the American people to the Red Cross for the fighting forces will be available for distribution through health departments. According to the announcement, health departments will apply to the Red Cross in Washington. It will be distributed subject to the condition that the person receiving the globulin may not be charged for it. Manufacturers and those concerned with distribution may not make any profit. The costs of processing and shipping are to be paid by the health department or other agency which is given a permit by the Red Cross. The price for an adult dose is estimated at about \$1.10.

The globulin is separated from blood by the Cohn process developed at the Harvard Medical School by Dr. Edwin J. Cohn, and under a coöperative project with the Office of Scientific Research and Development.

U. S. PUBLIC HEALTH SERVICE HEALTH EDUCATION FELLOWSHIPS AVAILABLE FOR MEN

The U. S. Public Health Service announces that, through the coöperation of the National Foundation for Infantile Paralysis and the W. K. Kellogg Foundation, additional fellowships for health education are now available for qualified men of certain Selective Service classifications as well as for women.

Fellowships will lead to a Master of Science degree in Public Health. They

will provide for 12 months' training in public health education, 3 months of which will be supervised field experience; \$100 a month for 12 months, full tuition and travel. Training will be given either at the University of North Carolina, Yale University, or University of Michigan.

Forms for application for fellowships may be obtained from the Surgeon General, U. S. Public Health Service, Washington 14, D. C. Applications must be accompanied by a transcript of college credits and a small photograph, and must be in the office of the Surgeon General not later than August 15, 1944.

INFANTILE PARALYSIS GRANTS

The National Foundation for Infantile Paralysis announces twenty-seven grants totalling \$1,128,770 for the nation-wide fight against infantile paralysis. The grants have been made to leading universities, laboratories, and other organizations throughout the country and will be operating by July 1. Three long-term programs, each covering a 5 year period, are included. Two are for the purpose of improving knowledge in the field of physical medicine made to the Medical School of the University of Minnesota and Northwestern University Medical School, and the third, made to the University of Michigan School of Public Health, will finance and operate an expanded virus study unit.

NORTHERN CALIFORNIA PUBLIC HEALTH ASSOCIATION

The following are the new officers of the Northern California Public Health Association elected at a recent meeting:

President—Dwight M. Bissell, M.D., San Jose

President-elect—Edward Reinke, Berkeley

Vice-President—Ann Wilson Haynes, San Francisco

Secretary—Margaret Beattie, Berkeley

Treasurer—Helen Hartley, Stockton

Representative on Regional Board, Western Branch, A.P.H.A.—Malcolm H. Merrill, M.D.

El Presidente

de la

República de Cuba

En uso de las facultades que le están conferidas por las leyes y a propuesta del Consejo Supremo de la Orden

Confiere:

la Condecoración de la Orden Nacional de Mérito

Carlos J. Finlay

en el grado de

Comendador

a la Sociedad Americana de Salubridad

Dado, firmada y sellada por el Ejecutivo de la República y refrendada por el Ministro de Salubridad y Asistencia Social, Gran Canciller de la Orden, en el Palacio de la Presidencia, en la Habana, a 3 de Diciembre de 1944.

Presidente.

Ministro.

Ministro de Salubridad y Asistencia Social,
Gran Canciller de la Orden.

Dr. Alberto Recio, Minister of Public Health of Cuba recently announced the opening of the National Institute of Hygiene in Havana which took place on May 17, 1944. On the occasion President Batista presented decorations of the Order of Carlos J. Finlay to Brigadier General James S. Simmons, Director of Preventive Medicine, Office of the Surgeon General, U. S. Army, Washington, D. C.; Colonel Harry Plotz, Chief of the Division of Virus and Rickettsial Diseases, Army Medical School, Washington, D. C.; Dr. Rolla E. Dyer, Director of the National Institute of Health, Bethesda, Md.; Dr. Reuben Kahn, University of Michigan, Ann Arbor, Mich.; Dr. Henry Hanson, Commissioner of Health of the State of Florida, Jacksonville, Fla.; and Dr. A. A. Moll, Executive Secretary of the Pan American Sanitary Bureau, Washington, D. C.

At the same time the Cuban Government presented decorations to the Rockefeller Foundation, the American Public Health Association (reproduced above), and a posthumous award to the American Yellow Fever Commission in honor of the great services rendered to yellow fever control.

UNIONS APPROVE PREEMPLOYMENT SYPHILIS EXAMINATIONS

Dr. J. C. Geiger, Director of Public Health, San Francisco, Calif., announces a new procedure in the Industrial Venereal Disease Control Program. The Bay Area Metal Trades Council, of the American Federation of Labor, unanimously passed a resolution approving voluntary preemployment serologic examinations which are conducted by management in cooperation with health departments.

Under the operation of this program voluntary preemployment serologic specimens will be secured by medical representatives of management. These specimens will be submitted to the laboratory of the City and County of San Francisco Department of Public Health. The results of these laboratory findings are referred to the local Division of Venereal Diseases. Information is kept strictly confidential between the health department and the individual tested. Information pertaining to the results of these examinations is reported neither to labor unions nor to management.

The Division of Venereal Diseases assumes responsibility of advising employees of positive serologic examinations. Industry is advised that it is not justified in considering the presence of syphilis in an employee under treatment or adequately treated as a cause for discharge from employment. Such an attitude is detrimental to the war effort, a hindrance to progressive industrial venereal disease control, and leads to plant management-labor union conflict.

"Latent syphilis is not a danger to industry. It is neurosyphilis and cardiovascular syphilis, the results of latent syphilis, which present the potential industrial hazard. The Health Department and not industry or labor unions must assume the responsibility for requiring adequate treatment of the

known, untreated, or inadequately treated syphilitic industrial worker. Only those workers who are not amenable to, or who do not respond satisfactorily to adequate treatment, should be placed in new occupations commensurate with their physical condition. Venereal disease case finding and case holding can be best managed by the Health Department as an unbiased official agency legally responsible for these activities.

"Failure of the employee to submit to voluntary preemployment blood tests under this industrial venereal disease control program will in no way jeopardize that person's chances of employment. The program, with the assistance of management and labor unions, will be put into practice in some of the large and small industrial plants under the direction of the Division of Venereal Diseases in San Francisco.

"From the start of this program labor has cooperated fully with the local health agency. The establishment of this program was made possible by the assistance of the California Social Hygiene Association, the cooperation of union officials, and the efforts of members of the Division of Venereal Diseases."

SIGNIFICANCE OF THE UNION HEALTH CENTER

Dr. Manfred Bowditch, the Director of the Division of Occupational Hygiene in the Massachusetts Department of Labor and Industries, has called the attention of the Managing Editor to the *Annual Report* for 1943 of the Union Health Center, New York City. This volume carries a foreword by Dr. Haven Emerson in appreciation of Dr. George M. Price, the founder of the Union Health Center, who died in 1942.

As Dr. Leo Price, the present director, says in his introduction, this report for 1943 is supplemented by historical and other data compiled in the course

of 31 years of experience in an uncharted field of medical service.

"The Union Health Center is a unique institution in American industrial medicine. Prior to its establishment there were numerous medical service plans but they were instituted and administered by employers, management and other agencies. They did not represent the effort of workers in an industry to solve their own health problems through their own coöperative effort. The difference between the ladies' garment workers' health program and others lies, therefore, in the fact that it was conceived and operated by a labor union.

"Today the Center is so large, both in physical size and scope of service, that it can no longer be regarded as an experiment. It stands as a proof that medical service for labor, operated under the control of labor, works and has a valuable place in the community."

No one interested in the subject of group medicine or in the provision of medical services to the general community can fail to be interested in this report.

DR. FERRELL TO DIRECT MARKLE FOUNDATION

John A. Ferrell, M.D., Dr.P.H., has been appointed Medical Director of the John and Mary R. Markle Foundation of New York, effective July 1. Since 1910 Dr. Ferrell has been connected with the Rockefeller Sanitary Commission and the International Health Division of the Rockefeller Foundation, most recently as Associate Director for the work of the Foundation's health program in the United States, Canada, and Mexico.

The Markle Foundation was established in 1927 and since 1935 has limited its activities to research in the medical and physical sciences and the area of its operations to the United States and Canada. The scope of the

program has recently been broadened during the war to include the virus diseases and tropical diseases. According to the announcement, the directors of the Markle Foundation contemplate the formulation of a long-term program of research in the fields of the medical and the physical sciences when conditions become favorable and anticipate the appointment of a permanent medical director. Toward the attainment of this goal the directors will have the assistance of Dr. Ferrell.

DR. STRODE APPOINTED DIRECTOR OF INTERNATIONAL HEALTH DIVISION

The Rockefeller Foundation has announced the appointment of George K. Strode, M.D., as Director of the International Health Division of the Foundation, succeeding W. A. Sawyer, M.D., who has retired as Director to become Health Director of the United Nations Relief and Rehabilitation Administration, Washington. Dr. Strode's association with the Foundation goes back more than two decades during which he has been assigned to a variety of responsibilities in several sections of the globe. Recently he has been in charge of the European office of the Foundation as Associate Director. He is a graduate in medicine from the University of Pennsylvania and a graduate in public health from Harvard School of Public Health.

KANSAS PUBLIC HEALTH ASSOCIATION

At a meeting held early in June the Kansas Public Health Association elected the following new officers to serve for the forthcoming year:

President—Leon R. Kramer, D.D.S., Topeka
President-Elect—Paul Haney, M.S., Lawrence
Vice-President—J. E. Wolfe, M.D., Wichita
Treasurer—Evelyn Hannon, R.N., Topeka
Secretary—Jane Taylor, R.N., Topeka
Executive Committee—D. D. Carr, M.D., Topeka; L. W. Rowles, D.V.M., Topeka; Jeanette Rosenstock, R.N., Topeka

CHILDREN'S BUREAU STAFF CHANGES

A. L. Van Horn, M.D., has been appointed Director of the Division of Health Services of the Children's Bureau, U. S. Department of Labor, Washington, succeeding Edwin F. Daily, M.D., who is on leave to serve with the U. S. Army as a Major in the Medical Corps. Dr. Daily will serve in reestablishing medical and hospital services in some of the liberated countries. Betty Huse, M.D., has replaced Dr. Van Horn as Assistant Director for Crippled Children in the Division of Health Services of the Bureau with which she has been associated since 1939.

Dr. Van Horn, who is a native of North Carolina, is a graduate in medicine of the University of Michigan Medical School, and was at one time Chief of the Bureau of Child Hygiene of the Ohio State Department of Health. Since 1936 he has been regional medical consultant for crippled children and for maternal and child health programs with the Children's Bureau, and in 1937 was made Assistant Director of the Crippled Children's Division, becoming Director in 1941.

Dr. Huse, who is a native of Nebraska, is a graduate in medicine from Cornell Medical College and was at one time connected with that institution in the department of pediatrics.

Dr. Daily has been in charge of the emergency maternity and infant care program administered by the Children's Bureau under which nursing and hospital care are given service men's wives and infants. He is a graduate in medicine of the University of Colorado.

MEDALS AWARDED FOR SERVICE ON
TYPHUS COMMISSION

It has recently been announced that medals for exceptionally meritorious service have been awarded to Captain Charles S. Stephenson, U. S. Navy;

Dr. Rolla E. Dyer, Assistant Surgeon General, U. S. Public Health Service; and Brigadier General James S. Simmons of the U. S. Army; all members of the United States of America Typhus Commission concerned with the control of typhus among United States armed forces overseas and with the prevention of the introduction of typhus fever into the United States.

PERSONALS

Central States

CHARLES F. ATKINSON, M.D.,† Health Officer of Missaukee, Kalhaska, Crawford and Roscommon Counties Health Unit, Traverse City, Mich., has been placed in charge of the Grand - Traverse - Leelanau County Unit, Traverse City, Mich., succeeding BUELL H. VAN LEUVEN, M.D.,† Saulte Sainte Marie, Mich.

LORIN E. KERR, M.D.,* who has been Health Officer of Lorain County, Ohio, has resigned to accept appointment as Surgeon (R), U. S. Public Health Service, and has been assigned as Regional Medical Officer of the War Food Administration with offices in Portland, Ore.

WILLIAM H. RUMBEL, M.D., of Hubbard, Ohio, was appointed Director of the Bureau of Dental Hygiene. Dr. Rumbel, who took over the post June 12, succeeds STEPHEN V. LUDDY, who left the State Health Department to take a position with the City Health Department of Alexandria, Va.

JAMES P. SHARON, M.D.,† Mount Pleasant, Mich., has resigned as Director of the Isabella County Health Unit to accept a position with the Mississippi State Board of Health, Jackson, Miss.

* Fellow A.P.H.A.

† Member A.P.H.A.

FRANK F. TALLMAN, M.D.,† who has been Director of Mental Hygiene in the State of Michigan for the past two and one-half years, is resigning to accept the position of Commissioner of Mental Disorders in the Ohio State Department of Public Welfare, Columbus, Ohio. There are 15 hospitals for the mentally ill, feeble-minded, and epileptic in the Division of Mental Diseases which Dr. Tallman will supervise, with a population of about 27,000 patients. In addition to his work with the hospitals, Dr. Tallman will be responsible for a receiving hospital program, and a state-wide program of mental hygiene.

Eastern States

MAJOR MEYER J. PLISHNER,† Sanitary Corps, AUS, of Framingham, Mass., after his recent promotion was assigned to the Medical Intelligence Division of the Surgeon General's office, Washington, D. C., where he is working under Lt. Colonel Gaylord W. Anderson, M.D.*

WILBUR A. SAWYER, M.D.,* formerly Director of the International Health Division, Rockefeller Foundation, New York, and who was recently appointed Director of Health, United Nations Relief and Rehabilitation Administration, Washington, now makes his headquarters with UNRRA at 1344 Connecticut Avenue, N.W., Washington, D. C.

HUGH H. SMITH, M.D.,† of the staff of the International Health Division, Rockefeller Foundation, has been appointed Regional Director of the International Health Division for the United States, Canada, and Mexico to succeed JOHN A. FERRELL, M.D.,

DR.P.H., who has become Medical Director of the John and Mary R. Markle Foundation, New York, N. Y. Dr. Smith has been a member of the staff of the International Health Division since 1930, serving in the New York Laboratories of the Division, in Jamaica, Brazil, Colombia and Great Britain, where he has been stationed for the last three years.

CLAIRE W. TWINAM, M.D., DR.P.H.,† former Acting Superintendent of Lakeville State Sanatorium, Middleboro, Mass., has been appointed to succeed CARL C. MACCORISON, M.D., as Superintendent of North Reading State Sanatorium, North Wilmington, Mass. In September, 1943, he was appointed Superintendent and Medical Director of the King County Tuberculosis Hospital, Seattle, Wash.

Southern States

ALBERT L. CHAPMAN, M.D., M.P.H.,† P.A. Surgeon, U. S. Public Health Service, has been detailed to Charleston, W. Va., as the Deputy Health Commissioner. Dr. Chapman assumed his duties on June 19. The Deputy Health Commissioner will be under the administrative direction of the State Health Commissioner to act as assistant in administration; to coördinate the activities of all bureaus and divisions of the department; to act for the State Health Commissioner in his absence; and to do related work as required.

ARTHUR P. RICHARDSON, M.D., Head of the Department of Pharmacology of the University of Tennessee, Knoxville, Tenn., has been appointed Head of the Division of Pharmacology of the Squibb Institute for Medical Research, New Brunswick, N. J., to become effective October 1, 1944. Dr. Richardson will replace

* Fellow A.P.H.A.

† Member A.P.H.A.

H. B. VANDYKE, M.D., who has accepted the position as Head of Pharmacology, College of Physicians and Surgeons, Columbia University, New York, N. Y.

WALTER J. RILEY, M.D.,† formerly of Sutton, W. Va., has been named Health Officer of District No. 4 at Weston, W. Va., to succeed CLAUDE A. THOMAS, M.D.

HENRY VAN D. STEWART, M.D.,† formerly of Little Rock, Ark., was recently appointed in charge of the Perry County Department of Health, Hazard, Ky.

DR. HAZEL K. STIEBELING has been appointed Chief of the Bureau of Human Nutrition and Home Economics of the Department of Agriculture, effective June 30, to succeed DR. HENRY C. SHERMAN, who will return to Columbia University. Dr. Stiebeling has for fourteen years been a leading nutrition expert of the Bureau. She was a member of the technical group at the United Nations Conference on Food and Agriculture at Hot Springs, Va. She is now a consultant of the United Nations Relief and Rehabilitation Administration.

JAMES P. WARD, M.D.,* Greenville, Miss., Director of the Washington County Health Department, has resigned to accept a position with the Standard Oil Company as physician on the Island of Aruba.

PAUL A. WRIGHT, M.D.,† Jackson, Ky., has been named Health Officer of Fulton County, Ky., succeeding Jesse M. Dishman, M.D., who was recently transferred to Benton, Ky.

Western States

JACOB C. GEIGER, M.D.,* Director of Public Health of the City and County of San Francisco, Calif., was granted

the decoration "Al Merito" by the Ecuadorian Government for "distinguished service, for noteworthy and indomitable leadership in the advancement of public health in the Americas."

The Wartime Health Picture in an English City

ARTHUR MASSEY, C.B.E., M.D.*

Medical Officer of Health, Coventry, England

COVENTRY has been well in the news during the present war, for at the time of the sustained enemy air attacks on Britain in 1940-1941, it was a "front-line" town and was, in fact, the first provincial town to suffer concentrated enemy bombing. It was the heavy attack on the night of November 14-15, 1940, which brought Coventry into the world headlines and added the word "coventrate" to the German vocabulary. Other equally bad raids were suffered in April, 1941, and there have been dozens of smaller attacks at various times.

These events are now past history. They are mentioned here only because of the health and social problems—immediate and remote—to which they gave rise or contributed.

EPIDEMIOLOGY

At the time of the air attacks, damage to drainage communications and water mains was extensive, and the typhoid hazard was real. Preventive

measures included (a) intensive local propaganda—by press, posters, and Ministry of Information loudspeaker vans—urging the boiling of drinking water and milk, (b) chlorination of water supplies, (c) facilities for anti-typhoid inoculation, and (d) steps to secure the early restoration of water pipes, sewers, and drains. On each occasion, the position was quickly cleaned up and no typhoid cases attributable to the raid conditions did in fact occur.

Apart from air raid damage, other wartime factors, such as abnormal movements of population, shelter life, overcrowded billets, and the like might well have been expected to bring serious epidemiological consequences. This happily has not been the case so far, as will be seen from Table 1 relating to cases notified locally.

In regard to diphtheria, the immunization campaign has been intensified during the war. At present 81 per cent of the school children and 46 per cent of the preschool children in the city have been immunized. The work is proceeding as fast as parental accept-

* Guest of the American Public Health Association at fourteen state and regional meetings during May and June, 1944.

TABLE 1

Year	Typhoid and Paratyphoid	Diphtheria	Cerebrospinal Fever	Scarlet Fever	Measles	Whooping Cough
1938.....	19	212	36	406
1939.....	4	277	11	831
1940.....	23	224	46	408	584	129
1941.....	27	258	53	166	1,414	476
1942.....	5	162	29	415	1,236	194
1943.....	2	103	18	610	2,223	372

ance will permit. We have some way to go in this matter before we can emulate the record of certain of your American cities.

During last winter, the first influenza epidemic of the war occurred. It began in November, 1943, and came to an end in January, 1944. The behavior of influenza during the war has been unexpected in that all misgivings in this connection regarding the "blitz" year (1940-1941) proved to be unwarranted. The 1943-1944 outbreak occurred unusually early in the season, and the anticipated recurrent wave in March did not materialize. The outbreak was not at all comparable with the grave epidemic of 1918. It was rather in the category of a "nuisance raid." The mortality was slight, but the loss of working time was considerable. During the outbreak, some 15 per cent of all employees in local factories, for example, were off work at any given time on account of influenza. The infecting agent was probably the same type of virus—virus A—as that first recovered in Britain in 1933.

A SHADOW ON THE HEALTH PICTURE

The increased incidence of venereal diseases has cast a dark shadow on the health picture. At the venereal dis-

eases treatment center there has been a wartime increase in attendances amounting to about 70 per cent.

The local problems of social hygiene are particularly difficult because of the absence of parental influences or of service discipline in the large numbers of young civilians drafted to the city from various parts of the country, for munitions work.

To aid the combat against venereal diseases in Britain, the Government some two years ago introduced Regulation 33.B. Briefly, this regulation gives powers to medical officers of health to require examination and treatment to completion of any person who has been cited by two venereal disease patients as the source of their infection and who is confirmed upon examination to be infected. Less formally, persons are followed up similarly who have been cited by one patient. The procedure introduced by the new regulation is proving most useful, although it has its limitations.

TUBERCULOSIS

There has been some wartime increase in pulmonary tuberculosis. The tempo and resultant strain of war work and, to a lesser extent, the difficulties of ventilation inseparable from the blackout of factories, offices, and dwellings,

TABLE 2

		Year					
Pulmonary Tuberculosis	Cases Notified	1938	1939	1940	1941	1942	1943
	Deaths	231	250	278	301	315	351
Non-Pulmonary Tuberculosis	Cases Notified	138	134	174	138	126	
	Deaths	67	58	62	50	61	53
		20	25	32	17	32	

are contributory factors. The wartime dietary can be exonerated.

The local increase in the incidence of the pulmonary form will be seen from Table 2, although the mortality curve is now falling.

HOUSING AND ENVIRONMENT

From 1942 onward, the local housing shortage has been marked. This is due to an increasing population, the virtual cessation of house building during the war, and the considerable loss of preëxisting houses through enemy action. Inexorably this has produced a degree of domestic overcrowding which would not be tolerated by peacetime standards.

The adverse repercussions are social rather than epidemiological.

A mitigating feature in regard to housing has been the large-scale public provision of excellent workers' hostels, each a village in itself.

In post-war housing plans, it is likely that prefabricated dwellings will have their place, at any rate for some years. Speed and economy of labor in erection rather than lower cost appear to be the points in favor.

Among the properties destroyed by enemy action were considerable numbers of houses that had been scheduled for slum clearance. The future slum clearance program for the city has thus been greatly simplified.

A sanitary problem of some importance has been occasioned by rat infestation of bombed sites, and energetic measures are in operation against this menace.

WARTIME DAY NURSERIES

Since 1941, there has been a comprehensive chain of day nurseries and nursery classes in the city. Their primary purpose is to care for the young children of married women who are willing to do essential war work and who cannot otherwise do so owing to

domestic ties. The nurseries provide a most valuable means of giving systematic medical and educational care to large numbers of children of pre-school age. Objections were raised by some against the policy of day nurseries on the ground that they were conducive to the spread of the common fevers. Experience in Coventry does not support this view.

NUTRITION

The available records of the school medical service and of the maternity and child welfare centers indicate a satisfactory state of nutrition among the child population. The figures shown in Table 3 relating to the nutritional state of school children, as ascertained by routine medical inspection, well illustrate this:

TABLE 3

Year	Percentages			
	Excellent	Normal	Slightly Subnormal	Bad
1938				
(pre-war)	27.62	63.84	8.49	0.05
1943	33.62	64.56	1.81	0.01

The meals and milk in schools scheme, and the Ministry of Food policy of supplying free to young children cod liver oil and fruit extracts are making a valuable contribution in the matter of wartime child health. The British Restaurants Movement, too, is helping in the maintenance of a satisfactory nutritional level in the adult population.

MENTAL HEALTH

The people of Coventry (as those of other "blitzed" towns) stood up well to the experiences of heavy bombing, and cases of neurosis resulting from the raids were few. Cases of true shell-shock were negligible.

It is evident that the average mind can withstand the occasional heavy stress better than continued smaller stresses. Thus in the prevention of

neurosis, depressing psychological influences must be removed. Locally the clearing up of bombed sites is one of the measures that have contributed usefully in this matter.

VITAL STATISTICS

The figures in Table 4 represent the vital statistics of Coventry in wartime and in the year immediately prior to the war, viz.:

TABLE 4

Year	Death Rate	Marriage Rate	Birth Rate	Infant Mortality Rate
1938	9.5	20.6	16.5	56.0
1939	9.4	24.3	17.7	54.6
1940	13.3*	25.7	16.4	63.0
1941	12.8*	24.5	17.1	54.8
1942	10.2	20.2	19.3	62.3
1943

* Including air-raid fatalities.

The local death rate is low if air raid deaths are excluded. The increasing birth rate is related *inter alia* to good economic conditions. The infant mortality rate is at present withstanding the impact of difficult social conditions of which an increase in illegitimacy is not the least important.

HOSPITAL POLICY

In Coventry the two large general hospitals—one voluntary and one municipal—sustained severe damage in the November, 1940, raid. Later, one was largely destroyed in the April, 1941, attack.

Certain temporary reconstruction works have been completed, and the situation has also been assisted greatly by the Ministry of Health group scheme under which routine evacuation of patients to outside group hospitals takes place. These emergency arrangements are meeting the wartime position.

After the war, both the Voluntary and the Public Hospital Authorities are faced with the task of completely reconstructing their general hospital services. It is a unique opportunity for securing an integrated hospital service and plans to that end are under discussion.

CONCLUSION

In the foregoing are set out briefly a few of the main public health topics of Coventry in wartime. The health picture shows both bright and dark features. The bright side is represented by a freedom from epidemics, a good state of nutrition, satisfactory vital statistics, and an excellent morale. On the black side are the increased incidence of venereal diseases and phthisis, housing shortage, and domestic overcrowding. On the whole, the health account is in credit. In regard to the city's vicissitudes through enemy bombing, some compensation is to be found in the enormous opportunity now afforded for bold and healthy town planning. The City Council is not likely to lose this chance of a future Coventry on model lines.

Slum Clearance

The Newark Plan

CHARLES V. CRASTER, M.D., D.P.H., F.A.P.H.A.

Health Officer, Newark, N. J.

SLUMS must go! These areas of depressed living conditions exist and have existed for centuries in every city of the world. It is here that poverty, crime, and disease go hand in hand to establish a reign of antisocial living which is a blot upon our present civilization.

A foreign writer who travelled in America recently, said of one of our large cities, "The wide boulevards, the green belt and lofty blocks of offices along the lake, extend for only a short distance inland. Then come square miles of slums as bad as anything to be seen in the East End of London, the Villette quarter of Paris or the Moabit district of Berlin. Small wonder that these suburbs have bred so many gangsters. I would willingly commit a great crime to get away from such an environment." (*Pioneers! O Pioneers!* by Saunders).

THE CAUSE OF SLUMS

A slum is defined as "a low filthy quarter of a city or town, a street or place where debauched and criminal persons live or resort." Such a description neglects, however, to mention that slums are directly associated with sub-standard housing conditions and, indeed, these are the direct causes of slum development. The definition goes further and indicates buildings in the last stages of dilapidation and structural disrepair. It usually indicates buildings so far gone in disrepair, as to be unfit for habitation according to our modern standards of living.

The slum is not so much a menace to humanity by itself, as by the persons who are forced by economic necessity to live there. These dwellings naturally attract the poor, the ignorant, careless, and criminal part of the community, where generally a total disregard of accepted methods of decent living are tolerated and sometimes preferred.

The congested slum sections of cities have developed as a result of the great immigration of workers from country districts attracted by the higher wages to be earned in our factories and industries. This influx of population found our cities totally unprepared to cope with the demands for adequate housing. These new workers were compelled, therefore, to seek accommodation in old dilapidated buildings, the relics of a former generation now dead and gone, or removed to other more desirable parts of the city. As city population increased, more and more of these old buildings were used up.

The majority of these old buildings were long past any usefulness as decent houses and were without any of the essential requirements of modern living. Thousands of our population are therefore, forced by economic conditions to live in premises without adequate lighting or ventilation, without sanitary plumbing, and without baths or other means for maintaining a good standard of personal hygiene.

The fire hazards are also high in these tinder boxes and at times the overcrowding causes the loss of life to be high when fires occur.

NEWARK'S SLUMS

Newark, like other large cities, has its full share of the slum problem. In this city, housing has been for many years an acute problem.

There are certain wards, particularly the third ward of this city, where the rate of house deterioration has been such, that many of the buildings used for occupancy of thousands of individuals are at present unfit for human habitation.

The onset of World War II with the consequent increase in the number of war workers has brought about undesirable and dangerous overcrowding. We are therefore faced with a steadily decreasing number of suitable homes and an increasing demand for them among our working groups.

In the survey conducted by the State Housing Authority (1934-1938) of a total of 44,451 dwellings located in Newark, 4,718 were declared unfit for use as dwellings, and 16,926 were found to need major repairs. In other words, approximately 50 per cent of the dwellings in the city had already deteriorated or were in a state of deterioration to such a degree as to make them unfit for habitation.

In the year 1934 a survey of the city housing situation was made by the local Health Department, under the Civil Works Administration program. The results obtained showed 8,558 families consisting of 57,636 persons living in overcrowded conditions, the majority of whom lived in the so-called slum areas.

Similarly in 1937, a survey by the City Health Department was conducted in the third ward. In this ward, all previous surveys had shown that slum conditions, overcrowding, bad housing, etc., were more generally present than in other parts of the city. The results of this survey were enlightening and revealed the following facts among 2,010 dwellings surveyed:

	<i>Per cent</i>
Dwellings in good condition.....	7
Major repairs were needed.....	54.2
Dwellings unfit for habitation....	14.8
Infestation with rats, mice and vermin	80
Sanitary violations existed.....	94
Dwellings built prior to 1902....	70

The greater majority of these sub-standard dwellings were without baths, private indoor water closets, or central heat.

SLUMS AFFECT HEALTH

Apart from the questions of crime and juvenile delinquency which are naturally more prevalent in slum areas, the effects of the depressed housing upon health is well indicated in the Third Ward Survey.

Tuberculosis morbidity rate in this ward was four times as great as for the rest of the city. The venereal disease prevalence rate was six times as great as for the city as a whole. The same holds true for all the other major epidemic diseases, the third ward showing an undue prevalence of all of them.

A famous Admiral once said "the speed of a convoy is the speed of its slowest ship." Thus the health of a city is in the main, the health of its slums as well as its sunbathed residential districts. The high disease and death rates in congested districts is counterbalanced by the low prevalence of disease in its better residential districts, thus establishing a mean or average rate which is not truly representative of the health of a population in every part of the city.

A comparison of the general death rates of the city with that of the industrial section known as the Ironbound District, showed that the latter had a death rate of 9.1 as compared with 12.6 for the rest of the city. In this section, although entirely low income, there was not the same congestion of the population and property dilapidation as existed in the third ward.

SHALL NEWARK BECOME A SLUM CITY?

The question which had to be considered was, "Shall Newark be allowed to sink into a morass of slum buildings and become a slum city, because of a lack of a program to bring about decent housing conditions?" The problem appeared to be a stupendous one, totally beyond our capacity as a city to solve without the spending of millions of dollars far beyond our ability to underwrite.

A limited step in this direction was made by the adoption of the Federal Housing projects which were initiated under the Wagner-Stegall Act, and subsequently the U. S. Housing Authority. Under this authority a \$14,000,000 program was adopted to provide homes for 2,469 Newark families in six separate projects. These projects were located in the areas of worst congestion and bad housing, and brought about the demolition of a considerable number of substandard dwellings. These housing projects were, however, only a drop in the bucket of our need for slum clearance, and up-to-date dwellings for our working population.

The results of the various housing surveys showed that there was a crying need for some long-range plan of concerted action by those whose responsibility it was to safeguard the health morals, safety, comfort, and general welfare of our Newark citizens. If this were done there could be no grounds for civil or criminal negligence charges, should a great fire or an epidemic of disease sweep through these city plague spots.

A city-wide demolition of all our substandard areas was out of the question, unless such buildings could be immediately replaced by suitable dwelling units. This was beyond our vision at this time, so we have preferred to wait for a federal or state plan as a post-war project. Such a project would call for the demolition of all slum

property and the reconstruction of dwellings in conformance with modern sanitation, fire and building regulation.

Faced with the situation of large areas of the city being in the slum class, with a steady deterioration of all dwellings more than fifty years of age, and a steady, increasing demand for more homes for war workers, it was very urgent that some plan be devised to salvage the slum property if it was possible to do so. Such a plan had to be along the following lines:

1. A city ordinance adopted making it mandatory for owners to remodel buildings in accordance with modern standards of living.

2. The rehabilitation of all substandard dwellings, bringing them up to modern sanitary, fire and building standards, in conformance with new housing regulations.

3. The demolition of those dwellings and structures beyond rehabilitation and declared to be unfit for use by the Building, Fire, and Health Departments.

Following these recommendations, the Newark City Commission, at the request of Director John A. Brady, Director of Public Affairs, had an ordinance passed July 14, 1943.

This ordinance entitled, "An ordinance to repair, close or demolish dwellings which are unfit for human habitation," had the following requirements:

1. The office of Supervisor of Rehabilitation of Dwellings, was created, the Health Officer of the city being designated to fill this office.

2. Upon the filing of a petition by a public authority, or by five residents of the city, or upon the Supervisor's own motion that there exists a substandard building which, due to dilapidation, disrepair, or structural defects, increases the hazards of fire, accident, or other calamities rendering the property detrimental to the health and safety of the residents, the Supervisor

is required to make a preliminary investigation.

3. If the Supervisor finds the condition to be as stated, he is required to serve notice upon the owner for a hearing upon the case.

4. The owners or parties interested have the right to file an answer at the time and place fixed in the complaint.

If the Supervisor, after the hearing, determines that the building is unfit for human habitation, he is required to serve notice on the owners and parties interested, as follows:

1. If the repairs, alterations or improvements of the building can be made at a cost not exceeding 50 per cent of the value of the dwelling, the owner is directed to carry out such repairs within a period of ninety days. The owner is given the option of vacating or closing the building within this period.

2. If the repairs or alterations cannot be made at a cost of less than 50 per cent of the value of the building, the Supervisor is required to make an order requiring the owner to remove or demolish the building within a period of 90 days.

If the owner fails to alter, improve or demolish the building within the period set, the Supervisor is required to put a notice on the premises saying, "This building is unfit for human habitation."

The Supervisor is authorized to rehabilitate or demolish any building in case of non-compliance.

The amount of the cost of any repair or removal or demolition of any building, remains as a municipal lien against the property upon which said cost is incurred.

Where there is money obtained by the sale of any material after demolition, the Supervisor is directed to deposit the same in the Court of Chancery, to be disbursed in such manner as the Court directs, to the owners or

parties in interest. Any person affected by an order of the Supervisor, may petition the Court of Chancery for relief, in accordance with Chapter 112 p.c. 1943. R.S. Cum. Supp. 40-48-2-3, *et seq.*

1. The Supervisor is authorized to investigate the dwelling condition in the city of Newark, in order to determine which dwellings are unfit for human habitation.

2. To administer oaths, affirmatives, examine witnesses, and receive evidence.

3. To enter upon premises for the purpose of making examination, provided that such entry shall be made in such manner as to cause the least possible inconvenience to the persons in possession.

To carry out the requirements of the ordinance a beginning was made with those properties known to be in the worst structural condition, irrespective of the location in the city. Inasmuch as the Building Department of the city had a list of many hundreds of buildings slated for demolition by reason of structural defects, it was considered advisable for the Supervisor to begin with the list to determine how far any of them could be salvaged for habitable purposes.

For the purpose of obtaining a coördinated report upon each property to determine the extent of sanitary, building, and fire prevention defects, a score card was drawn up to be filled in for each dwelling.

This report known as the Unfit Dwelling Record, has a full description of the building with a photograph of the structure at the time of investigation. The various defects are scored by giving a maximum score of 100. The conditions recorded in the score are:

Type of house
Age
Rental
Heat
Condition
Toilets

Baths
 Water supply (hot or cold)
 Light rooms (natural or artificial)
 Ventilation (front, rear, or cross)
 Dark or windowless rooms
 Interior painting
 Plumbing (modern or old)
 Toilets (inside building or porch)
 Floors
 Accident hazards
 Vermin infestation
 Roof gutters and leaders
 Exterior repairs
 Cellars dry with cement floor
 Foundations

Any dwelling failing to attain a minimum score is declared unfit for human habitation.

HEARINGS

Hearings before the Supervisor take place every 2 weeks, at which time representatives of the Building Department, the Fire Prevention Bureau, and the Health Department are present to give evidence upon their reports submitted.

The difficulties so far encountered are, the need for searches for titles where the owners are unknown, or where a number of owners of an estate have to be contacted, frequently living in distant parts of the country and abroad. The Supervisor is unable to take action for rehabilitation or demolition, until all the owners or parties at interest are located and permission is obtained. These searches constitute quite a large part of the work of the Supervisor. No demolition can be ordered by the Supervisor until the proper owners can be established. The same holds true for the rehabilitation of slum property, until sufficient funds shall have been appropriated by the City Commission to make property available for habitation, where the owner refuses to carry out necessary repairs.

Of the 25 cases so far coming before the Supervisor, 6 buildings were either rehabilitated or demolished; 3 were

removed from the custody of the Supervisor because of the nature of the tenancy, 9 are pending action within the 90 day period allocated for demolition or rehabilitation, 7 are awaiting action by the Supervisor, the owners having failed to respond to the hearing notices issued by the Supervisor.

The clearance of slums made possible by this ordinance, will depend upon the amount of money appropriated for demolition and repair of slum dwellings. The most practical method would be for a city to establish a revolving fund to be used for demolition and rehabilitation when the owner cannot or will not do the work. The 50 per cent value clause would make the eventual return to the fund a certainty. Provision could be made for such advances to be on a loan basis and an annual return with interest added to current taxes for a reasonable period of years.

The action by the city along these lines has, however, had the effect of making the owners of slum property consider the carrying out of repair and reconstruction where this is possible. Inevitably, the dwellings so far gone as to be impossible of reconstruction within the city will come before the Supervisor for immediate demolition orders.

SUMMARY

Slum clearance is a public health problem of major importance in all large cities in the United States.

The structural disrepair of dwellings has an important bearing on the health of the inmates.

Thousands of people are compelled to live in slums where lighting, ventilation, sanitary needs such as baths and toilets are much below modern standards of living. There is dangerous and unhealthy overcrowding in these areas.

In a State housing survey of the City

of Newark, N. J., in 1934-1938 in a population of 400,000, there were 4,718 houses declared unfit for habitation. Of the 44,451 surveys of dwellings, 16,926 were in need of major structural repairs. Of the dwellings of the city, 50 per cent had already deteriorated to such a degree as to make them unfit for habitation.

In a survey of one of the worst wards of the city, among 2,010 dwellings surveyed only 7 per cent were found in good structural condition. In that ward, the tuberculosis morbidity rate was four times as great as for the rest of the city and the venereal disease prevalence rate was six times as great.

Under the Wagner-Stegall Act, the federal authorities built six projects to provide housing for 2,469 families. This is a drop in the bucket of our real need for housing. Inasmuch as the complete removal of slums must await adequate federal or state funds it was considered advisable to institute a program of salvage for the city with compulsory demolition or rehabilitation of all dwellings declared to be unfit for living purposes. A city ordinance was adopted, creating the position of Supervisor of Rehabilitation of dwellings. Under this ordinance, any slum building which could not be rehabilitated for a sum not exceeding 50 per cent of the assessed valuation was required to be demolished. The cost of demolition remained as a lien upon the property.

Under this ordinance, the Supervisor could order the rehabilitation of any slum building should the owner refuse

to do so. The owner of any slum building could be ordered to appear before the Supervisor and present his case for consideration. A score was adopted that covered all the sanitary defects of the building, all its structural and fire hazards. The difficulties so far encountered were the searches for titles to determine correct ownership, as many of the owners are out of the city or abroad.

Sufficient funds must be appropriated by the city government to cover the cost of demolition of outworn property. The creation of the office of Supervisor has started machinery in motion that will encourage the owner of slum property to consider rehabilitation rather than to allow such dwellings to become useless for living purposes.

CONCLUSIONS

The subject of slums in our large cities cannot be ignored by public health authorities. The slum must go! It is a blot upon our modern ideas of fair living conditions for our workers and should not be tolerated. If funds for complete demolition of slum property are not available, then salvage of many dwellings is within the bounds of possibility. At least, dwellings utterly unable to be renovated should be removed.

In all plans for remodelling of slum property, a decent standard of repair should be insisted upon, with the idea of making all changes meet modern standards of house construction.

An Epidemic of Acute Anterior Poliomyelitis in El Salvador, C. A.

JUAN ALLWOOD-PAREDES, M.D., M.P.H.

*Bureau of Communicable Diseases, Direccion General de Sanidad,
El Salvador, C. A.*

DURING the past year, 1943, a definite outbreak of poliomyelitis occurred in this country, El Salvador, a total of 64 paralytic cases being reported. Diagnostic spinal fluid examinations were done on only 6 cases but the clinical symptoms and signs were checked in all cases except 10 by two or more physicians, and often by four or five. In addition, 17 cases were seen by a consultant in orthopedics. The number of cases given is undoubtedly not absolutely complete because most of the physicians of this country are located in the larger cities; however, it is our belief that practically all paralytic cases were known because the small total area of the country, the density of population (232.5 sq. mile) and the distribution of the health officers, made it possible for the latter to visit or see all the paralytic cases and also visit all suspicious cases which came to their knowledge either through physicians' reports or through indirect channels or even hearsay (see Map. No. 1).

It might be noted that the physicians of this country have considered poliomyelitis a rare disease and the great majority of them acknowledge that they have never seen a case, but there is no doubt that the disease has occurred here because occasional individuals of various ages are seen at times who exhibit the typical sequelae of infection with the virus of poliomyelitis.

In considering the reported cases, only 61 have been used, as there is a little doubt about the other 3. There is no question that the incidence of this disease was well above the usual average, although it is true that this year added impetus to interest in the disease was given by the fact that a child in a rather influential family was among the first ones to become ill and had some residual paralysis. The figures for case incidence during the previous 5 years are not dependable because of the obvious low numbers, and were secured from local hospital records. They follow: 1938—1 case (Hóspital Bloom); 1939—0 cases; 1940—7 cases (2 Hospital Bloom, 5 Hospital Rosales); 1941—1 case (Hospital Rosales); and 1942—1 case (Hospital Bloom). It is possible that a small epidemic may have occurred in 1940 when 7 cases were seen in the local hospitals, but we can only surmise that other cases may have occurred and been unattended.

In 1943, 3 cases were seen before the month of May, namely, 1 in January in San Salvador, 1 in February in Quezaltepeque, and 1 in April in Mejicanos, a small village in San Salvador. In this same village a case was reported on May 29, in a house on the 8a. Calle Oriente. This was a child of 5 who died in 4 days with pharyngeal paralysis. Eight days later a second case appeared in the same neighborhood in a girl of 2 years. This was the

MAP 1

daughter of a man who had returned from California 13 days before. Seven days later a 3 year old sister of the 5 year old child was reported to have the disease. This case and one observed in July were the only ones reported in which more than one case occurred in any one family. The fourth case occurred in a child of 4 months, being at N. 24th Ave. at a considerable distance from the other cases. From this time on no apparent continuity of spread of cases could be determined.

During the first week of July when there had already been 5 cases in San Salvador, the first of 2 cases was seen in the village of Mejicanos, and a week later the first of 4 cases in Villa Delgado. The proximity of these towns to San Salvador might suggest some relationship.

The time sequence and distribution of paralytic cases (see Map No. 2) might suggest that the epidemic showed a radiation from San Salvador (the capital city) as a center, and followed some of the principal routes of communication, viz., the Pan-American Highway, the Highway to Zacatecoluca,

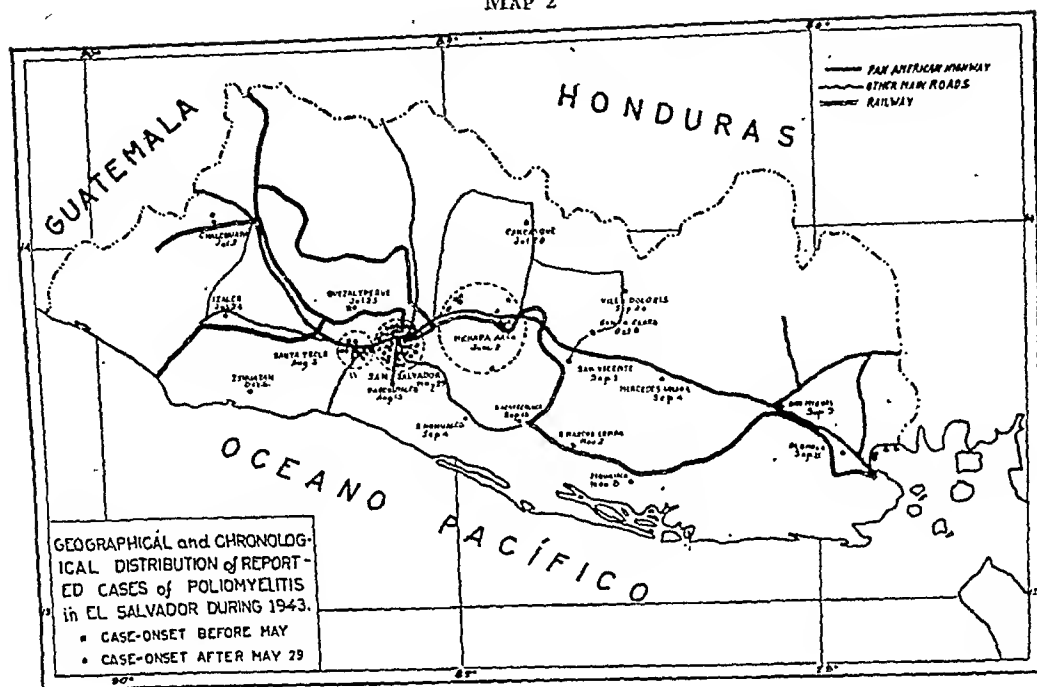

the railway to the East. Of course, the number of cases is not sufficient to draw definite conclusions in regard to this supposition.

The following chart shows how the cases seemed to radiate from San Salvador as a center.

Date	Locality	Cases
<i>Toward the East:</i>		
July 2	Santa Cruz Michapa,	1
July 8	Cojutepeque,	3
Sept. 1	San Vicente,	1
Sept. 4	Mercedes Umaña,	1
Sept. 9	San Miguel,	1
Sept. 11	Olomega,	1
<i>Toward the South:</i>		
Aug. 15	Panchimalco	1
<i>Toward the Southeast:</i>

<i>Toward the Northwest:</i>		
July 23	Quezaltepeque,	1

Five more cases: 1 in Chalchuapa July 10, 1 in Izalco July 24, 1 in Canasque July 28, 1 in Ishuatán October 6, and 1 in Villa Dolores September 4,

MAP 2

show a more sporadic distribution and are probably related to the normal endemic crop.

In observing the distribution of cases it may be noted that 2 minor outbreaks occurred in 2 separate distinct areas (see Map No. 2). One of them we shall refer to as the outbreak in the Michapa Area and the other as the outbreak in the Santa Tecla Area. The Michapa Area includes the towns of Santa Cruz Michapa, Cojutepeque, San Martin, Perulapán, El Rosario, and Paraíso de Osorio and covers an area within a radius of 18 kilometers of Michapa. There were 10 cases in this area, 9 of which were visited, examined, and confirmed by the local health officer for that district.

The first case in this area was noted in Michapa on July 2, following 3 more in Cojutepeque (July 8, August 20 and 27), 3 in Perulapán (July 25, August 6 and 14), 1 in San Martín, and another in Paraíso de Osorio, August 21, and the 10th case in El Rosario, September 4. It has been suggested that these might be an aftermath of a fair held at Perulapán from June 25-29.

The outbreak in the Santa Tecla Area occurred in a locale about 2 km. wide and 6 km. long on the Pan-American Highway, between kilometer 8 and kilometer 14 to the west of San Salvador. Eight cases were observed and reported here. The first case appeared in the city of Santa Tecla, August 3, the 2nd on a coffee finca in the suburbs, to the west of the city on the Pan-American Highway, August 8, the 3rd and 4th in Santa Tecla on August 12 and 14. The 5th and 6th on a coffee finca 4 km. to the east of the city on the Pan-American Highway, September 3 and 4, the 7th in the city of Santa Tecla on September 9; and the 8th on the coffee finca "Santa Elena" 2 km. to the east and also on the Pan-American Highway. Because of the efficient coöperation between the local health officer and the physicians in this area it is believed that probably all cases here were reported.

As one may see in Table 1, the peak of the epidemic was reached in the San Salvador Area in the week ending July 24; in the Michapa Area, the week ending on August 14, and in the Santa

Tecla Area, on August 25. The epidemic reached its apex for the whole country in the week ending August 7.

The localities of the first group are of a purely rural character, and therefore may be taken as an index of the rural incidence of poliomyelitis in El Salvador.

Table 3 indicates a high incidence in the localities of rural character, and also, in the City of San Salvador.

" III—20,000 to 50,000	223,949	16	7.1
" IV—More than 100,000	106,926	22	20.6
Total	442,347	61	13.7

In this respect the same proportion has been maintained, as has been reported in other epidemics of poliomyelitis.

The marked incidence in younger age groups is rather typical, apparently, of the age distribution of this disease in warm climates.¹ Attention might also be drawn to the fact that in New York City in 1916 70 per cent of the cases occurred in children under 5 years, and in 1915 only 34 per cent of the cases reported were in this age group: likewise the figures given for an epidemic in Cuyahoga County, Ohio, vary from 51.2 per cent in children under 5 years in 1930 to only 19 per cent in this age group in 1941.² These figures are typical of an apparent trend toward a higher median age in localities or coun-

tries where the disease has been reported for several decades. No definite explanation is given for this change.³

It is believed that the reporting of cases in El Salvador this year was sufficiently complete so that the age distribution given is a true one. (A similar high figure for this age group was reported by Dr. German Castillo of Nicaragua at the Fifth Congreso Medico Centroamericano held at San Salvador, El Salvador, in 1938. At this time he read a paper on the outbreak in Managua in the same year, 1938, in which epidemic 42 cases were reported to and seen by him in his capacity as special investigator for the Health Department. Of these 42 reported cases, 97 per cent were children under 5 years of age.)

Four deaths were reported as due

directly to the disease in children between 2½ and 5 years of age. This represents 6.5 per cent mortality of the entire series and 18 per cent in this particular age group. One case of unique interest occurred in a child only 23 days of age, reported by Dr. Miguel A. Luna of Santa Tecla, in which the diagnosis was later confirmed in consultation by five other physicians.

With the exception of the 4 cases which died and showed a bulbo-spinal type of involvement, the rest showed only spinal localization. Fever was the most constant symptom, accompanied in 47 per cent of the cases by coryza and/or pharyngitis. There was nausea and vomiting in 20 per cent of the cases, and diarrhea in 27 per cent. Some showed meningismus, and a few had brief periods of convulsions. Fifty per cent complained of muscular pain.

The interval between the onset of the disease and the development of paralysis varied within rather wide limits. As a rule it was observed between the 3rd and 8th days. In 3 cases it was not noticed by the original attending physicians. In 1 case paralysis was not discovered until the 20th day.

In the primary examination given to 17 patients (this was given anywhere from 16 to 30 days after the onset of the disease, depending on when the consultant was called) by Dr. León Avila Jr.,* orthopedic consultant, the following localizations were found:

<i>Location</i>	<i>No.</i>
Left lower limb.....	5
4 limbs and trunk.....	2
4 limbs	2
2 inferior limbs.....	2
Lower right limb.....	2
Lower left limb and trunk.....	1
Upper and lower right limbs.....	1
Upper right limb.....	1
Upper right limb and lower left limb	1

Of the 45 muscles, or muscular groups affected, those that were most frequently affected are as follows:

Group I

(70% of the cases)
External flexors of the left leg

Group II

(64% of the cases)
Medius and minor left glutei muscles

Group III

(59% of the cases)
Left major gluteus muscles
Internal flexors of the left leg

Group IV

(53% of the cases)
Left quadriceps
External rotators of the left thigh

Group V

(47% of the cases)
Right major gluteus
Major and minor right glutei
Left posterior tibial

Group VI

(41.1% of the cases)
Internal rotators of the left thigh
Left tensor fascia lata
External flexors of the right leg
Adductors of the left thigh
Left anterior tibial
Left peroneus longus
Left peroneus brevis
Left flexor digitorum longus

The first case that was known to the Dirección General de Sanidad was one that occurred during the 2nd week of July. It might be noted that 10 cases had occurred prior to this but had not been reported at that time. However, the Sanidad promptly made contact with the Chief of the Consultorio Infantil of the Hospital Rosales where there is a satisfactory register of morbidity, and it was discovered that there was an obvious rise in the number of cases that had been observed during that same week. Consequently, the physicians of the country were notified to be conscious of the possibility of the presence of an epidemic, the authorities of public education and sports were also

*The aid of Dr. León Avila, Jr., as orthopedic consultant was made possible by the financial assistance of the Servicio Cooperativo Inter-Americano de Salud Pública, an agency of the Dirección General de Sanidad and the Institute of Inter-American Affairs, Division of Health and Sanitation, El Salvador.

notified and the schools and swimming pools were closed. As soon as possible a small pamphlet giving the essential known data and urging medical attention in all suspected cases was prepared and distributed through various channels to the general public.

An interesting sidelight on the promptness with which a physician was called to see such cases before and after this program of education was begun is given in Table 4.

TABLE 4

Number and Percentage of Cases Seen by the Physician in the Indicated Number of Days After the Onset of the Disease, in the Cities of San Salvador, Santa Tecla, Cojutepeque, San Vicente and San Miguel, Before and After Warning the Public

CONCLUSIONS

1. The 1943 poliomyelitis epidemic occurring in El Salvador involved 61 known patients.

2. Analyses are given showing geographical distribution, seasonal occurrence, age distribution, and known main symptoms.

3. The age incidence of reported cases, 90 per cent occurring in children under 5 years of age, is unusual; but no definite explanation for this can be given, although the observation has been made several times that with this infection the median age is often very low when cases first begin to be reported from a given locality.

4. Public warning of the presence of this epidemic was followed by definite shortening of the time lapse between onset of the disease and first medical attention.

ACKNOWLEDGMENT: The author wishes to acknowledge the kindly advice and criticism of Major J. R. Hobbs, M.C., A.U.S., Medical Officer of the Field Party of the Institute of Inter-American Affairs in El Salvador, and also, of Dr. Howard A. Howe and Dr. Kenneth F. Maxcy of the Johns Hopkins School of Hygiene and Public Health.

An Epidemic of 3,000 Cases of Bacillary Dysentery Involving a War Industry and Members of the Armed Forces*

C. H. KINNAMAN, M.D., F.A.P.H.A., AND
F. C. BEELMAN, M.D.

*Director, Division of Epidemiology; Secretary and Executive Officer;
Kansas State Board of Health, Topeka, Kansas*

ON Saturday, September 12, 1942, a telephone message was received from a practising physician of Newton, Kans., that a severe outbreak of intestinal disorder was occurring in that city. Arrangements were immediately made to send Board of Health personnel to that city and they arrived Sunday morning, September 13.

Newton is the county seat of Harvey County, located in the southeastern section of Kansas, approximately 26 miles north of the City of Wichita. The population was 11,048 in 1940, and apparently there has been little change in the last two years. The population is predominately white, with approximately 1,200 Mexicans and 1,400 Negroes. The topography is gently rolling, sandy loam draining to Sand Creek, a tributary of the Arkansas River, which flows in a southerly direction through the western section of the town.

The main war industries in Newton are the railroad shops, yards, and division offices of the Atchison, Topeka and Santa Fe Railroad, the Ponca

Tent Company, and flour mills. Approximately 700 persons living in Newton at the time of the epidemic were employed by airplane factories in Wichita. The local public health personnel included a part-time county health officer and a full-time veterinarian milk inspector.

The source of the public water supply is derived from eight drilled wells having an average depth of 125 feet, located 8½ miles southwest of the city, and is used by more than 95 per cent of the population. The wells are pumped to a surface reservoir and the water is re-pumped from this reservoir into two high service mains. These mains are 12" and 14" in size and approximately 8 miles in length before they connect to the distribution system of the city.

The milk shed includes 24 dairies, 4 delivery companies, 2 local pasteurization plants, 1 pasteurizing plant operated by the Santa Fe, and numerous smaller dealers. The known daily milk consumption is 1,300 gal., of which 900 gal. are raw milk and 400 gal. pasteurized. The city operates under the Standard Milk Ordinance, which requires the services of a milk inspector and laboratory for supervision and enforcement of the ordinance.

* Presented at a Joint Session of the Epidemiology, Health Officers, Maternal and Child Health, and Laboratory Sections of the American Public Health Association, at the Seventy-second Annual Meeting in New York, N. Y., October 14, 1943.

There are approximately 30 public eating establishments served by 200 food handlers. The city maintains no supervision or control over these establishments or employees.

The city sewage system is modern in every respect and more than 80 per cent of the houses in Newton are connected to the system.

Upon arrival in Newton, immediate contact was made with physicians of the city and information received indicated that the outbreak was explosive in nature and the geographical distribution was uniform over the entire city.

Samples of water from the city wells and distribution system were taken at once. On Monday, September 14, samples taken from the deep wells showed no contamination; however, those from various points on the distribution system were heavily contaminated. City officials were notified and chlorination of the city water supply by means of an emergency chlorinator at the pumping station, installed by State Board of Health engineers, was started.

Hand-bills were printed, advising citizens to boil all water used for drinking purposes, and prohibiting the sale of milk that had not been pasteurized. Air raid wardens distributed these hand-bills to every home in the city.

As the water department of the Santa Fe Railroad has orders to empty the water tanks on all passenger coaches and fill with the "99.9 per cent pure" Newton water, as advertised by city officials, the division superintendent of the A. T. & S. F. Railroad, was immediately ordered to discontinue the use of Newton city water on passenger trains until such time as it was proved safe for drinking purposes. The City Water Superintendent was given instructions to shut off all public drinking fountains and immediately open fire-hydrants and flush out the water mains.

On Tuesday, September 15, addi-

tional personnel of the State Board of Health arrived with laboratory equipment. Headquarters were established and an epidemiological case study of the city was started by health workers. Fifteen nurses, registered with the Civilian Defense organization, volunteered, and were used to block canvass the city to obtain case histories of sick persons.

Laboratory workers obtained stool specimens from hospital cases and a general sample at large.

Early studies of the case reports revealed a massive, generalized, sudden and severe epidemic of dysentery. The average case persisted for approximately 3 to 6 days, and listed as symptoms were weakness, nausea, vomiting, cramps in stomach, persistent diarrhea, and occasional bloody diarrhea. The only possible vehicle was the water supply.

Sanitary engineers checking systematically the distribution system discovered the following defects:

1. Seven cross-connections between the public water supply and private sources of water
2. Seven cross-connections between the public water supply and sewerage system, plus 13 flush tanks in the sewerage system in which the water inlet was below the discharge level of the tank, and a large number of basement ejector pumps located in private residences

After carefully checking all of the above cross-connections, it was apparent that the source of the contamination had not been discovered.

Epidemiological factors indicated that a large amount of contamination was introduced into the water system at a point from which it could be rapidly circulated through the entire distribution system.

This conclusion was based upon the following factors uncovered in the epidemiological and laboratory studies:

1. Generalized distribution of cases
2. Massive infection of the population

CHART 1—Showing attack rate by age groups

3. Explosive nature of the epidemic

4. Bacteriological analysis of water samples obtained over the distribution system

Upon receiving additional engineering assistance from the District Office of the U. S. Public Health Service, there was a review and discussion of the survey on the distribution system, and efforts to locate the source of contamination were intensified.

On September 18, 4 days after emergency chlorination had been started, the tests showed that a satisfactory chlorine residual was being maintained in all parts of the city. Repeated satisfactory bacteriological analyses having been obtained, the water was released as safe, Saturday, September 19.

A bit of information, which proved of extreme importance, was received from a Santa Fe Railway water department employee who said that a sewer block had occurred at a Mexican vil-

lage on the southwest outskirts of the city about the time that dysentery cases developed in the city. On Sunday, September 20, an inspection of the water supply, plumbing and sewage disposal of the Mexican village was made by our sanitary engineers.

Contrary to previous statements by city officials, that no change had been made to the distribution system, further information uncovered the fact that changes had been made on the two main supply lines entering the city at a point close to this Mexican village. It developed that on September 7, an 8" stub and valve were removed and replaced with a 20" stub and valve. The water pressure was off 9 hours while these changes were made. The next morning, September 8, it was found that the 20" gate valve had slipped and the section of the 14" supply line was again taken out of service for more than 3 hours, during

which time the 20" gate valve was straightened and permanently anchored.

This work was performed by a private contractor, under the supervision of the City Water Superintendent. Our investigation showed that a service connection came from this 14" main to the Mexican village and supplied three frost-proof hydrants and two water closets equipped with twelve frost-proof toilets. The frost-proof hydrant pits and each of the pits under the water-closets had a drain connection to the sanitary sewer, which had previously been blocked.

Evidence that these pits had been filled with sewage so that it had covered the drain openings in the valves of the frost-proof hydrants, and also the drain connection in the frost-proof toilets, still remained at the time of our inspection.

The hydrants were the only source of water for the Mexican families and the water-closets were used by approximately 112 persons living in the village.

In reconstruction of the situation, when the water pressure was off on September 7 and 8, persons in the village, attempting to get water, apparently opened the valves and, not obtaining water, left them open; this, in turn allowed the sewage backed up in the box to flow through the drain opening into the water main. It is not unreasonable to assume that a person attempting to get water and finding it shut off, would leave the valve open, allowing a continuous flow of sewage through the drain opening. That these valves were open was brought out in later testimony by one of the workers on the mains, who turned them off when the main was put into service. Persons using the water-closets would automatically operate the valves controlled by the seat and thus allow sewage to flow into the water main.

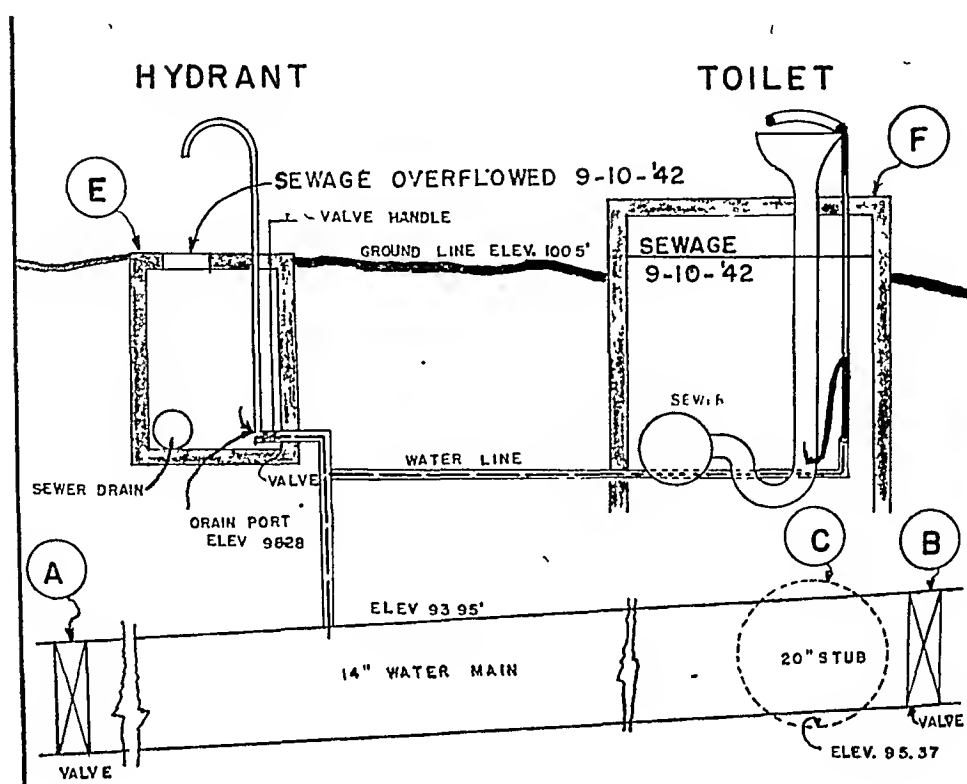

Each time the water main was out of service, only a small amount of water was flushed out of the line before it was placed back in service, and no attempt was made to sterilize it.

Levels were run on the mains and the water take-off to the Mexican village. Since the elevation of the water main was lower at the point of this connection than where the stub was changed, a considerable amount of sewage would remain in the water main after the line was again in service.

In order to prove to city officials that this was possible, conditions equivalent to those at the time the mains were being worked on were reconstructed. Drainage to a hydrant pit was blocked and water placed in the pit, covering the drain port of the frost-proof valve. The hydrant was left partially open, the water line was disconnected at the main and, within a few minutes, dye placed in the hydrant pit was flowing from the disconnected line at the main. Certainly sewage covering those same ports, under similar conditions, would flow into the water main supplying the distribution system of the city. Additional evidence showed that the first 7 cases reported occurred among the Mexican families living in the bunk-houses, and that persons who did not drink water in the city, but did drink from taps on the two supply mains taken off before the water reached the Mexican village, were not infected.

A study of the case histories indicates that slight contamination of the city water supply evidently began about August 1. One hydrant valve in the Mexican village was in bad condition and would not close. Inhabitants of the village were in the habit of emptying sewage through the screen trap in the floor covering the hydrant pit. There were 82 persons who reported they became ill during the month of August, and 124 persons reported the

CHART 2—Schematic charts showing evident flow of sewage entering main

date of onset of their illness to be during the first 6 days of September.

We do know, from a study of the recording manometer on the distribution system, that uniform water pressure was being maintained under great difficulties. In fact, this led to the changes which were made in the distribution lines to include an additional storage tank near the Mexican village. Other cross-connections previously listed may also have been responsible as sources of contamination of the city water supply at times of low pressure.

The epidemiological investigation revealed that the peak onset occurred on September 10, with 743 persons giving this date as the beginning of their sickness. As a result of the epidemic, business in the city was practically at a standstill on Thursday, September 10, when it is estimated about 2,000 persons were ill.

In the face of such massive infection of the population, local newspapers carried stories on September 11, quoting city water officials regarding the city water, as saying, "a constant check-up by analysis is made, and reports this week are, that the water is absolutely pure and healthful; there are no open mains, no seepage into the distribution system and no chances of contamination." On September 12, the papers carried a story, stating that the part-time county health officer, residing at a small rural village, was in the city and had made all possible investigations into the numerous cases of illness, which, for want of a better diagnosis, were referred to as "intestinal influenza." The newspaper quoted him further as saying that he was unable to find any evidence whatever that the prevalence of the illness was in any way due to trouble with the city water supply or the supply of milk and other dairy products from the regularly inspected dairies; that the same illness had been prevalent in the country, all neighboring towns, and, in fact, all over the Middle West. He also stated that "during damp season, when excessive rains have continued for extended periods, there is much illness of this nature affecting the stomach and bowels." It was his expressed opinion that "a period of a week or so of sunshine would practically clear up the illness."

Because of these stories in the daily newspaper and statements made by various local authorities, our investigation was seriously handicapped for several days before satisfactory cooperation was established with city water officials. Because of inadequate health service and lack of supervision by city officials of the municipal water system, the citizens of Newton were misinformed regarding the cause of the epidemic. If adequate investigations had been made as soon as cases first

began to occur in August, it is possible that this epidemic might have been prevented.

Laboratory examination showed the predominating organism recovered from the stools of sick persons and from the intestinal mucosa in fatal cases, to have been *Shigella paradysenteriae*, Flexner group (Hiss.).

From scattered cases traceable to Newton, it is assumed there were many cases other than those occurring in the city, since a large number of trains were supplied with water at this station.

There were 2,871 regular passenger cars (Pullman and coaches) supplied with water between the dates of September 3 and the afternoon of September 14, at which time the water was prohibited for use by interstate carriers; also, a large number of troop trains were serviced during this same period.

Histories were obtained from 150 trainmen, who were off duty on account of illness and undoubtedly there were many other railroad employees, who could not be interviewed because of their absence from the city.

Eighty-one employees of the Ponca Tent Company; working on war materials, were also off duty because of illness caused by drinking city water. Two hundred and fifty employees of airplane factories working in Wichita, who lived in Newton, were off duty because of dysentery during the epidemic.

As a result of the Newton epidemic:

1. The State Legislature passed new laws giving additional authority to the State Board of Health to supervise public water distribution systems.

2. Local funds were made available for a health unit.

3. The city plumbing code was revised and put in force, eliminating all cross-connections.

4. Water specimens are being taken at weekly intervals at designated places in the distribution system.

5. Emergency chlorination of the city water supply became a permanent procedure.

SUMMARY

1. An outbreak of more than 3,000 cases of dysentery, with several deaths at Newton, Kans., was evidently caused by sewage entering the water distribution system of the city through frost-proof hydrants and water-closet valves.

2. Failure of the Water Department to sterilize or flush that portion of the distribution system where changes had been made, led directly to heavy infection of the public.

3. Hazardous cross connections, found in the distribution system at times of low pressure, without chlorination, may have been responsible for

previous sporadic cases of intestinal disturbance.

4. A great number of war workers were absent from their jobs for several days; an unknown number of soldiers and civilians were infected; the ordinary business of the city was disrupted for a period of 3 days; and important transcontinental trains, many of them troop trains, were delayed an average of 1 hour while taking water at a nearby safe supply.

5. With institution of proper public health protection measures, the epidemic quickly subsided with no further outbreak of cases reported from the city.

Dye Concentration in Resazurin Tablets*

C. K. JOHNS, PH.D., F.A.P.H.A.

Associate Bacteriologist, Division of Bacteriology and Dairy Research, Science Service, Dominion Department of Agriculture, Ottawa, Ontario

ONE drawback to the widespread use of the resazurin test has been the necessity for weighing out accurately small quantities of the dye powder in the preparation of a solution of the desired strength. When it was learned in 1941 that standardized tablets were being made available in Britain, steps were taken to interest American dye houses in the preparation of similar tablets, since it was intimated that permits for the export of British tablets were unlikely to be granted during the war. In consequence, a batch of tablets was prepared by the National Aniline Division of the Allied Chemical and Dye Corporation, and samples were submitted for testing. When solutions prepared from these tablets were compared with those prepared from the powder (Eastman) in use in this laboratory, the former were obviously much weaker. It was therefore suggested to the manufacturer that the strength of the tablets be increased. This was done, and solutions prepared from the second batch (No. 10550) were found to agree very closely with those made up from Eastman powder.

When similar tests were run on tablets from two English manufacturers it was discovered that they also were much weaker. Since the English tablets were first made up from Eastman resazurin powder,⁵ it was suspected that

there were marked variations in the dye content of different batches of their powder. With this in mind, a portion of the batch of dye used by Ramsdell, *et al.*⁴ was obtained and tested out against several batches of Eastman resazurin. It was found that the batch used in Britain to standardize both their tablets and their resazurin comparator discs² was approximately 22 per cent weaker than that used by Ramsdell, while the batch we had been using, and against which the National Aniline tablets had been standardized, was approximately 25 per cent stronger.

In view of the fact that in England both tablets and comparator discs² had been standardized against the weaker batch of dye, the writer was reluctant to recommend a stronger concentration for American tablets. However, after extensive tests with both British and National Aniline tablets had been made, it was the unanimous opinion of the collaborators* that the stronger concentration was preferable. Although it showed slightly more bacteriostatic effect, requiring about 30 minutes longer to reach the pink or white stages with the better grades of milk, it did not appreciably affect the time required to reach the P 7/4 Munsell color standard used in the

* Contribution No. 187 (Journal Series) from the Division of Bacteriology and Dairy Research, Science Service, Dominion Department of Agriculture, Ottawa, Canada.

* Thanks are due to A. Moldavan, Guaranteed Pure Milk Co., Montreal, and to J. Vanderleek, Clark Dairy Ltd., Ottawa, for making extensive comparative tests with the several batches of tablets and powder.

triple reading test.³ On the other hand, the stronger solution had an advantage in the greater ease of color differentiation, particularly with those milks which give a greyish tinge to the dye-milk mixture. Again, where the resazurin test is being applied to cream, or to abnormal milks such as colostrum, there is a decided advantage in the use of a stronger solution.

Through the courtesy of Robert S. Breed, a Lovibond comparator of the type used in Britain for determining the degree of reduction of resazurin in milk² was made available for study. A number of workers in this laboratory have compared this method with the one ordinarily used here (Munsell color standard papers in test tubes), and all agree that the latter is much more convenient and enables closer estimation of color than does the comparator method. It seems unlikely that the comparator method, involving as it does the removal of each tube in turn from the rack, placing in the comparator, finding the matching disc, and returning the tube to the rack, will ever be popular with users of the test in America. Consequently the adoption in North America of a dye strength greater than that used in the standardization of the

British comparator discs is unlikely to cause any serious inconvenience.

It is most unfortunate that the various batches of Eastman resazurin should have differed so greatly in strength. It is even more unfortunate that the batch used in England for the standardization of the test should have been weaker than that used by Ramsdell, *et al.*, while the batch used by us was stronger. However, for the reasons indicated, it has been considered desirable to standardize on a stronger dye concentration on this continent. A batch of tablets of the approved strength has recently been approved by the Biological Stain Commission¹ and is now on the market. With these on the market one of the biggest objections to the use of the resazurin test will have disappeared.

Tomorrow's Opportunities in Tuberculosis Nursing

DOROTHY DEMING, R.N., F.A.P.H.A.

*Consultant to Merit System Unit, American Public Health Association,
New York, N. Y.*

PREDICTIONS that we would have a rise in the tuberculosis death rate as a result of war conditions in this country have thus far been happily unfilled.¹ While more previously existing unknown cases have been discovered as a result of mass examinations and x-ray routines among the military forces and industrial workers,² even that total has not been staggering. It has, however, served to remind us that in 1942 only 7 states met the recommended standard of one hospital bed for every three annual deaths from tuberculosis.³ We urgently need more hospital beds and personnel to serve them. Nor do we know what the prolonged strain of war may do to our national resistance. Already tuberculosis, which Sir Arthur MacNulty so aptly calls the "camp follower of war," has taken heavy toll in Europe, reaching almost epidemic proportions in some countries, notably Poland.⁴

As this article is being written, premature and over-optimistic reports have appeared in the popular magazines⁵ of cures produced by a new drug, Diasone, a member of the sulfa drug family.^{5a} It is to be hoped that Diasone may be a forerunner of other sulfa derivatives giving more certain promise of aid to tuberculosis patients, so that our post-war efforts may be solely directed toward the prevention of new cases and the slogan, "Wipe Out Tuberculosis by 1965" will be realized, thanks to chemo-

therapy, but in the meantime, the American Trudeau Society points out⁶ that clinical and roentgenological data are inadequate to support a positive evaluation of the curative effects of Diasone and its use is not without hazard to patients. For the moment, we must pursue the course of proved efficacy: an early diagnosis, rest, nourishing food, nursing care under medical supervision, and return to an activity suited to the individual's strength. In this curative program, the public health nurse has a strategic rôle as nurse and teacher.

In 1943, reports showed that 80 per cent of the available hospital beds for tuberculosis (79,860) were occupied, the daily census showing an average of some 65,000 patients,⁷ while medical and nursing staffs in tuberculosis hospitals had been just about cut in half by the demands of military service. A survey made by the American Trudeau Society in 1942 indicated that out of 247 sanatoria, 85 per cent filled, 25 had 40 or more patients per graduate nurse.⁸ Actual visits to eleven typical sanatoria in October, 1943, revealed a 52 per cent curtailment of graduate nursing staffs employed in normal times.⁹

In the world of tomorrow authorities have already foreseen the need for an additional 44,000 beds for tuberculosis patients,¹⁰ making a total of 123,860. Can we count on adequate graduate

nursing staffs for these patients? In all probability we can, for we will have by 1946 the largest supply of employable graduate nurses in history—some 350,000 if the hoped for rate of production (65,000 students a year) is attained. This is about 1 nurse to every 361 persons in the population. It provides 4 nurses to every physician. Inasmuch as we were keeping only 225,000 nurses busy in 1935, it appears safe to plan now not only to restore normal service which has suffered so considerably from war shortages, but also to take advantage of this unprecedented surplus of nurses to improve the general care of tuberculosis patients. Here, for example, are tuberculosis clinics which at present report their service "shot to pieces" or actually discontinued by war shortages of nurses,¹¹ others in which teaching programs have been steadily reduced so that they consist in handing the patient a booklet and hoping he can read it. All sorts of nursing short cuts, some of them potentially dangerous to patients and others, have been necessitated in our hospitals.¹² If in three years we are going to have more nurses than we ever had before, if we are to have federal funds for advanced preparation in the clinical fields, then it is not too early to start building a foundation for more and better nursing care of the tuberculous. We must be ready for smooth and rapid expansion after the war. Preparation in this specialty becomes even more pressing in view of the federal appropriations made by Congress in June of this year to the U. S. Public Health Service for the control of tuberculosis.

EDUCATIONAL PREPARATION IN THE SPECIALTY

As a beginning, it is vitally important that students now in schools of nursing receive better fundamental preparation in tuberculosis nursing than

they have had in the past. In 1937 only 29 per cent of all the students (1,840) graduating from 101 schools of nursing in New York State had had tuberculosis nursing.¹³ More affiliations with tuberculosis hospitals during basic training are called for. In those schools which can offer only limited communicable disease experience for nurses, one would say such an affiliation in tuberculosis care was essential. For graduate nurses, refresher courses should be provided, especially for those who have missed this type of experience in their schools of nursing, or who have been long away from the field. Funds for clinical courses in the specialties are even now available (under the Bolton Act) to public health nurses and other nurses interested in this field. In 1943, Mt. Morris Tuberculosis Hospital, Mt. Morris, N. Y. (a state district hospital), "refreshed" ten public health nurses by a 6 week experience, and is repeating the plan this year. Many of the well equipped sanatoria offer unusual chances to nurses for experience in hospital administration. One can picture several of the new county hospitals of 100-300 beds offering very adequate practice fields for nurses specializing in hospital administration.

SAFEGUARDING SERVICE

One point, however, bears stressing: preliminary to promoting tuberculosis hospitals as practice fields for refresher courses or for student experience should come further immediate research into safe nursing technics. Except for the more thorough application of what we knew twenty years ago—tuberculin testing and x-ray—we cannot claim to have discovered any new means which can be relied upon to protect our young doctors and nurses from contracting the disease while caring for open cases. Tuberculosis in young nurses still shows a higher incidence than among other girls in this age group.¹⁴ Nurses still break down

with distressing frequency—and this not alone in tuberculosis hospitals but in general hospitals as well. We are more on the alert to prevent breakdown; we test with tuberculin and examine with x-ray more frequently; experiments with BCG vaccine continue but are far from conclusive and, in the meantime, infections occur. Nor do the infections seem to have much relation to the practice of present-day technics.

Some institutions use masks, gowns, and caps; some gowns only; some depend on good basic hand-washing routines and individual isolation technics for open cases, and yet the infections occur under all conditions. No one *knows* how to prevent tuberculosis among nurses and doctors who must be in fairly constant contact with positive sputum cases. If the portals of entry are solely the nose, mouth, and possibly eyes, is there no device to serve as an effective screen over this limited area? Or may the source of infection during bed rest, at least, be effectively walled off by a curtain of ultra-violet light around a patient's bed?

We have not shown much progress in controlling the environment in which the nurse must work in caring for tuberculosis—all sorts of mechanical devices are still unexplored. Here is a hospital so constructed that nurses, doctors, and ward helpers must manipulate dozens of doors or the same door a dozen times while giving daily care, the same door which the ambulatory patients may use. Is this a situation which an "electric eye" could remedy? Here is a hospital where nurses must overload their dressing and supply carts because patients are not provided with individual equipment; another where scarcity of washstands makes it necessary for the nurse to walk fifty yards to wash her hands. In many hospitals, patients are not grouped according to their infectiousness, partly because ward units are not flexible, partly because of

medical preferences. Hence a nurse must wear a gown in certain rooms and not in others; here is a book handled by a positive case; here is a "safe" book—it is little wonder a nurse feels happier when she treats all cases as infectious. The more nurses we have, the greater should be the chance for self-protection, since time may be taken for proper technics and nurses need not be overworked to the point where they grow fatigued, careless, and susceptible to infection.

NEW OPPORTUNITIES FOR SERVICE

It is gratifying to look ahead to the years when we will have ample nursing service in homes, clinics, and hospitals, but it is even more exciting to consider the new opportunities for service. There will be many suggestions for better care of the tuberculous growing out of the abundant life which peace promises; at least four fields—now lying fallow—await cultivation:

1. *Instruction of Patients and Families—*

At the present time, nurses in tuberculosis sanatoria are conscious of gaps in the instructions given by community nurses to patients at home before hospitalization and, when patients return from the hospitals, the community nurses find they, in turn, have to teach some of the lessons which it would appear patients should have learned during their long stay at the sanatoria. There would seem to be a need for a classification of instructions, something that might roughly correspond to graded lessons: certain essentials should be taught in the pre-hospital period, repeated, enlarged, and advanced during the cure in the hospital. While in the hospital and before returning home, a patient should show himself capable of putting certain lessons into practice for the protection of others and the maintenance of his own recovered health. On his return, the community nurse

would carry on the *leçons* of living safely with others. The supervision of such graded lessons at home, in hospital, and at home again could well be the job of a specially prepared public health nurse, working through the usual staff (hospital) and field (public health) nurses.¹⁵ There would surely be definite improvement in the patient's own understanding and handling of his disease, fewer breakdowns, and, most important perhaps, fewer new cases developing among contacts.

2. Educational Responsibilities Within the Hospital—

The opportunity to carry on an educational program within the hospital offers a full-time job in itself. Here a qualified nurse—preferably a public health nurse—would have no less than six possible groups of “students” with which to work:

1. The patients
2. Patients' families and friends who come as visitors, who need far more instruction than they are getting now in self-protection, behavior at the bedside, preparation for the patients' homecoming, and answers to their questions. Many hospitals give the visitors printed instructions. Sometimes these are thrust into the handbag and read a week later, sometimes they are dropped in the ward, sometimes given to families who cannot read, and most frequently they are read, forgotten, disregarded, and disobeyed.
3. Student nurses in affiliation
4. Graduate nurses: new staff and those taking refresher courses
5. Nonprofessional paid help.
6. Volunteers

A versatile teacher indeed is needed for these six groups which represent all grades of intelligence and varying levels of instruction.

3. Home Follow-Up—

For the most part, follow-up of discharged sanatorium cases is now carried on by the community nurses—county, local health department, or visiting nurse associations. This is as it

should be to avoid a specialized staff and duplication of home visits, but it is also evident that the sanatorium needs a liaison nurse—preferably a public health nurse—who takes over the supervision of service to patients getting ready to go home, sets in motion the community service to the home before the patient returns to it, and is assured that continued service is given the home and patient after the patient's return. This same supervising nurse could also be the one to see that the referring agency received reports of the patient's progress in the sanatorium during his cure. She would be the one to relay questions or problems which disturbed the patient during his cure and, in short, take upon herself many of the duties handled by medical social workers in general hospitals.

4. Rehabilitation—

More nurses should prepare themselves to serve in the field of rehabilitation when post-war funds for special education are available to nurses. This is a field which should appeal to many. It is a growing field of service to tuberculosis patients.

Nurses frequently complain that work in a tuberculosis hospital after the first year or two is monotonous and discouraging, forgetting that they have the best possible foundation of training and experience for advanced preparation in some related specialty. The farsighted director of nurses does not let her graduate staff stagnate; she rotates their responsibilities, observes and encourages their special aptitudes. She offers them opportunities to attend outside meetings, visit other institutions, keep abreast of special training opportunities, and she suggests further study when good work warrants it. After the war when pressures relax, may we not see rotation of nurses in wider arcs than in the past? For example, exchange experience between public health nursing

and tuberculosis hospital staffs, between city and country sanatoria, between East and West, North and South—all to the end that patients and families may be better served, understand tuberculosis more thoroughly, and be instrumental themselves in preventing the spread of the disease.

SUMMARY

This article has attempted to show that tuberculosis patients have a first lien on our attention after the war because of (1) their probable numbers, (2) the need to restore adequate care now greatly reduced by staff shortages, (3) the ample supply of nurses. It anticipates an increase in nursing service to tuberculosis patients at home, in clinics, and in hospitals; it urges attention to better protection of nurses from infection, better fundamental preparation of nurses in knowledge and care

of the disease, and suggests new opportunities for nursing service in combined hospital and community programs.

Problem of Control of Tuberculosis in Mental Hospitals with Reduced Personnel*

GEORGE W. WEBER, M.D., AND ROBERT E. PLUNKETT, M.D.

New York State Department of Health, Albany, N. Y.

AND

FREDERICK MACCURDY, M.D.

Commissioner, New York State Department of Mental Hygiene, Albany, N. Y.

THE high prevalence of tuberculosis in institutions for the treatment of mental diseases has long been known. In New York State during the 3 year period 1939-1941, the average annual death rate from tuberculosis (all forms) in the 26 state hospitals for the mentally ill and defective was 593.6 per 100,000 population, as compared with the average rate of 46.8 for the state as a whole. Although the patient population of these institutions during this period represented only 0.6 per cent of the entire state population, it accounted for 8.1 per cent of all tuberculosis deaths.

While no complete statistical data were available regarding the tuberculosis morbidity in these institutions, isolated studies made in recent years gave sufficient evidence to warrant the conclusion that morbidity among mental patients is far in excess of that found in the general population.

For years the State Departments of Health and Mental Hygiene had recognized the seriousness of this situation

and the need for corrective measures, but it was not until 1941 that a complete study became possible, chiefly because of the realization of the increasing cost to the state for compensation for tuberculosis to employees of the state mental hospitals.

The two departments, therefore, agreed to undertake the development of a control program based on the following points:

1. X-ray examination of all individuals, patients as well as employees, in each institution
2. Segregation of all patients found to have clinically significant tuberculosis
3. Referral to tuberculosis hospitals of all employees found to have clinically significant tuberculosis
4. Routine x-ray examination of all new patients and all candidates for employment
5. Periodic x-ray examination of employees assigned to duty in tuberculosis wards
6. Periodic resurveys of all institutions
7. Basic training in tuberculosis to be given in the state tuberculosis hospitals to members of the medical and nursing staffs to enable them to carry on the program in each hospital
8. Development of facilities for the treatment of tuberculous inmates, particularly of those whose mental condition would warrant their early discharge
9. Establishment of a system of records which would provide clinical, epidemiological and statistical data

* Presented before the Epidemiology Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 12, 1943.

Inasmuch as the fluoro-photographic method had proved itself economical as well as practical for mass x-ray studies, two 4" x 5" fluoro-photographic units were purchased and the necessary staffs for their operation were appointed. The x-ray surveys were started late in the summer of 1941 and have been continued for the past two years.

As in the case of almost all other civilian activities, this program also has been adversely affected by the war situation and the resulting man power shortage. Although most eager to cooperate with us in the development of the plan, the Mental Hygiene Department authorities have been wholly unable to carry out some of its provisions, principally because of the lack of trained personnel and the increasing turnover of employees. How serious the personnel situation is, is indicated by the fact that on April 1, 1943, the beginning of the fiscal year, there were 5,559 vacancies among the 22,147 positions available in all the mental institutions, and that in nine hospitals, which normally would have a total of 7,758 employees, no less than 3,809 candidates for employment were examined during the twelve months following our first x-ray survey.

Under the circumstances, it was inevitable that some phases of the program had to be either modified or postponed until such a time as the situation became normal again.

For instance, the almost daily shifting of employees from ward to ward, as a result of vacancies, has made it impossible to carry out the plan of establishing permanent staffs of nurses and attendants for the tuberculosis wards and of giving them the specialized training necessary to take care of tuberculous patients who are mentally irresponsible. Such a step not only would have made possible the application of proper prophylactic measures in the tuberculosis wards and the periodic

reexaminations of these employees, but, together with the concentration of all infectious cases in a few hospitals, would also have reduced the total number of employees exposed to tuberculosis. Nor has it been possible to give any consideration to the plan of offering graduate training in the state tuberculosis hospitals to physicians of the mental hospitals in order that they may assume, in collaboration with the Division of Tuberculosis, the task of continuing the application of control measures and of eventually developing a well rounded program for the study and treatment of the tuberculous patients.

However, in spite of these handicaps, steady progress has been made toward a clear definition of the tuberculosis problem in the mental institutions and of the steps necessary for its solution. It is felt, therefore, that sufficient information is now available to warrant a brief report of the most significant results of these two years' activities.

As of August 31, 1943, surveys had been completed in 23 state hospitals and state schools during which a total of 82,586 patients and 16,716 employees had been x-rayed. Still left to be surveyed are 3 hospitals with a total of approximately 9,000 patients and 1,400 employees.

Analysis of the findings among the 68,743 patients x-rayed in the first 20 institutions shows that 3,220, or 4.7 per cent, had x-ray evidence of clinically significant tuberculosis, while an additional 3,151, or 4.6 per cent, had tuberculous lesions which from the roentgenologic point of view could be considered as apparently healed.

The prevalence of clinically significant tuberculosis was not uniform in all institutions, ranging from a minimum of 0.4 per cent in one state school to a maximum of 8.0 per cent in one state hospital, the average being 5.3 per cent among patients of the mental hospitals

and 2.4 per cent among patients of the state schools for mental defectives. In the total group the rate for men was higher than that for women, 5.3 per cent as compared to 4.1 per cent.

In formulating the program it had been intended that all patients with clinically significant tuberculosis should be segregated, and that, if possible, this should be accomplished by concentrating them in a few of the better equipped and more centrally located hospitals. However, it soon became apparent that this plan could not be carried out completely. On the one hand the number of patients requiring segregation proved to be larger than expected, while on the other, shortages of equipment and materials made it impossible to effect the necessary alterations and improvements in the hospitals selected for this purpose. Up to the present time it has been possible to concentrate only 1,412 of the 3,220 tuberculous patients in 3 hospitals, while for the segregation of the remainder it has been found expedient to utilize whatever facilities for isolation were available locally in the other hospitals.

Among the 14,228 employees of the 20 institutions first surveyed, 156, or 1.1 per cent, showed x-ray evidence of clinically significant tuberculosis, 1.3 per cent of the men and 1.0 per cent of the women. An additional 359, or 2.5 per cent, had apparently healed lesions. The finding of 1.1 per cent with significant tuberculosis among mental hospital employees indicates that there is almost twice as much tuberculosis in this group of workers as in other general industrial occupations.

The original program provided that employees found to have clinically significant tuberculosis were to be referred to the state, county, or municipal tuberculosis hospitals of their legal residence for further diagnostic study and treatment if necessary. However,

the experience of the past two years in securing prompt hospitalization has been rather disappointing due to problems of residence, domestic and financial difficulties, and the unwillingness of some of the employees to enter local tuberculosis hospitals. Therefore, ways and means should be found, probably through legislation, to afford these employees an opportunity for immediate hospitalization as state charges. It is to be noted that the State of Michigan has recently enacted legislation to meet similar needs in that state.

Routine x-ray examinations of all newly admitted patients and of all candidates for employment have been established in every hospital after the original survey had been completed, the patients found to have clinically significant tuberculosis being segregated soon after their admission.

Analysis of the findings among 12,794 first admissions to 20 hospitals and state schools shows that 351, or 2.7 per cent, entered the institution with clinically significant tuberculosis, 3.9 per cent of the male and 1.6 per cent of the female patients.

Among the first 5,735 applicants for employment who were x-rayed, 61, or 1.1 per cent, were found to have clinically significant and 203, or 3.5 per cent, apparently healed tuberculosis. The applicants of the first group were referred to the proper health authorities for further follow-up.

It will be noted that the prevalence of clinically significant tuberculosis in this group of prospective employees is as high as that found among the old employees and again twice as high as that to be found in the general population. Further analysis of the information available will be necessary before this fact can be fully explained. However, it should be remembered that with the armed forces and better paying industries drawing the best of the available man power, the mental institutions

have been obliged to pick much of their personnel from lower socio-economic groups among which the incidence of tuberculosis is known to be higher than the average. Many of the new employees, particularly men, are in the older age groups, and recently an appreciable number of them have been coming from the South. In this respect it must be noted that while 1.6 per cent of the male applicants were found to have clinically significant tuberculosis, the rate was only 0.6 per cent among the female applicants, which group has been less affected by the war conditions.

Although the shortage of personnel has prevented the completion of the primary surveys in all institutions, resurveys are being started wherever possible. One such resurvey has just been completed in a state hospital and a preliminary analysis of the results shows that 23 new cases of clinically significant tuberculosis had developed among 2,275 patients who were first x-rayed two years ago, that is an incidence rate of 1.0 per cent in two years. It is obvious that the segregation of all the infectious cases found in any given environment as a result of a single survey will not prevent the occurrence of new cases in that environment. Therefore, it is necessary to reexamine the populations in these institutions at regular intervals, the frequency of these resurveys to be determined by the results of those now being conducted.

These surveys have produced a wealth of clinical and statistical data which when completely analyzed and correlated should contribute to our knowledge of the epidemiological and clinico-pathological aspects of tuberculosis and its relationship to mental diseases. So far, our study has served the purpose of outlining in definite terms the magnitude of the tuberculosis problem in the mental institutions.

Continuing and more detailed ob-

servations will be necessary before determining the factors which are more directly responsible for the high prevalence among the patients. Certainly, the theory advanced by several psychiatrists and supported by some statistical evidence that a specific biologic relationship exists between schizophrenia and tuberculosis cannot be discounted altogether. That not all the cases of tuberculosis found among the patients develop as a result of infection contracted during their residence at the hospital, is indicated by the fact that 2.7 per cent of them already have clinically significant lesions at the time of their admission, a much higher prevalence than that in the general population. It is interesting that as early as 1909 Gantner noted that many schizophrenics had tuberculosis before their admission to the hospitals.

On the other hand, close and prolonged contact, which is unavoidable in mental institutions, lack of appropriate prophylactic measures, and the inability of many of these patients to carry out minimum sanitary precautions, are other factors which must play an important part in the spread of the disease. Our experience shows that the prevalence of tuberculosis is directly related to the length of residence in the hospital. Only 2.8 per cent were found to have clinically significant lesions among the patients with less than 6 months residence in the mental hospitals as compared to 6.6 per cent among those with more than 5 years residence.

Whatever the causes, it is evident that measures to improve the situation have been long overdue and that they should be fully applied as soon as conditions permit. This should be done not only as a matter of duty to the patients and to the employees who care for them, but as a matter of basic public health policy.

The high prevalence of tuberculosis in 26 mental institutions deserves as

much attention as would a comparable prevalence in 26 other communities in the state.

It is known that up to 1941, the total number of new cases of tuberculosis diagnosed and reported every year had shown a general downward trend, the average annual decrease in New York State between 1936 and 1941 being 386. Less known is the fact that an increasing number of patients are being discharged every year from the mental institutions, particularly as a result of a wider application of shock therapy methods and of the system of paroling patients to family care. In 1941, 10,505 patients were discharged, and if the prevalence of tuberculosis among

them was the same as that obtaining among the patients in the institutions, nearly 500 cases of clinically significant tuberculosis, many of them being unreported because unknown, were introduced into the communities and homes.

It is evident that mental hygiene hospitals make up one of the major reservoirs of tuberculous infection. Public health and hospital administrators cannot afford to ignore this fact.

NOTE: All the statistical data were compiled and analyzed by Mary E. Thompson. Her invaluable assistance and advice in the preparation of this paper are gratefully acknowledged.

Modern Hospital Competition

To encourage the building, in areas where they are needed, of small hospitals that are efficiently arranged, suitable for smaller communities, creditable in architecture, simple in design, in good taste, economical to build, to operate and to expand and that make maximum use of the best ideas in planning and construction; to *furnish* to the trustees of small hospitals ideas that will stimulate them to provide better accommodations, and to *encourage* architects to give more attention to the designing of good small

hospitals and community health centers, The Modern Hospital Publishing Company offers six awards in each of two competitions

1. For the best designs for a small general hospital
2. For the best designs for a small community health center.

Any architect can obtain full details of the competitions by addressing an inquiry to The Modern Hospital Publishing Co., Inc., 919 North Michigan Avenue, Chicago 11, Illinois, by September 5.

Health Education in Nutrition*

Adapting Business Promotion Technics to Public Health Education

ANNABELLE DESMOND AND LEONA BAUMGARTNER,
M.D., F.A.P.H.A.

*Department of Public Health and Preventive Medicine, Cornell University
Medical College, New York, N. Y.*

THERE is a tool on the desk of the American business man which should be carefully examined by health educators the country over, because it could be of great service to health education if adapted to meet public health needs. That tool is promotion. Some educators have been hesitant to use it, thinking its bite is too sharp or perhaps too superficial. Yet if skillfully used, business promotional technics can be adapted to health education to further a cause or a program just as effectively as they are used in business to promote a product, a person, or a company.

Timing is one of the most important factors in the use of promotion. One must reap a full harvest of public opinion, and then the cause or program gains momentum rapidly, especially when there is real need in the community for the education presented. Promotion can offer a short cut to the objective. But this is not enough. Results become tangible and deeply

rooted only if this promotion is skillfully coördinated with painstaking follow-up instruction.

Since the European war began no health program has been in the lime-light so prominently as nutrition, and certainly none has benefited more from favorable public opinion. Yet the American consumer was not ready when the nutrition crisis came. When the need for rationing arose in the United States, fear amounting almost to panic seized the home front. To the average consumer, rationing meant reduced standards of living and some imagined a state of slow starvation. Now, after a period of rationing, the consumer is thoroughly conditioned by education and experience. The public may not have had all the varieties of food it wanted in 1943, but it had plenty of healthful food. This has been due in great part to the nation's farmers, who are winning the battle of food production. The nation's per capita consumption of all foods in 1943 was approximately 5 per cent above the 1935-1939 level, and was richer in essential nutrients.

No small element of success on the food front has been due to the instruction of people to eat the foods that their bodies require. In every American community, nutritionists, health educators, dietitians, farm agents, home

* This study was carried out under the auspices of the Kips Bay-Yorkville District Health Committee of New York City in conjunction with the Department of Public Health and Preventive Medicine, Cornell University Medical College.

The authors acknowledge the assistance of the members of the staff of these organizations, of the Department of Health, of the many community organizations, and of the lay and professional volunteers who made the project herein described possible. They are particularly indebted to Dr. W. G. Smillie, Professor of Public Health and Preventive Medicine, and to Mrs. William S. Ladd, Chairman of the District Health Committee.

demonstrators, school teachers, home economists, public health nurses, housewives, volunteers from all walks of life have instituted what may be termed as an all-American nutrition education campaign. Nutrition has had a field day. Hardly a hamlet in the country has been untouched.

Some programs have been more effective than others. Where some have failed, others have succeeded, and sometimes the results have been unusual. A notable example is the program in the Kips Bay-Yorkville area in New York City in which business promotion technics were utilized in carrying out its projects. Here 245,000 people reside in the heart of Manhattan, 45 per cent of them, in normal years, earning less than \$1,200 annually. The district, with its penthouses on Park and Fifth Avenues, its slums on First and Third Avenues, has the greatest income differential of any area of comparable size in our nation. Here is a cross-section of many nationalities, of many professions and trades, of rich and poor, of families and single boarders—in short, an ideal test tube for any health program because it contains so many and so varied characteristics of the typical American city.

The nutrition program began in January, 1942—a month after Pearl Harbor. It began in a citizens' health committee which is attached to the local health center. This center houses the municipal Department of Health staff and clinics for the district, a medical college's department of public health, and several voluntary health and social agencies. The health center is affiliated with an adjacent large hospital and medical school. Donated funds only were available for the program, so it began on the proverbial shoe string.

The staff consisted of a community organizer from the field of business

promotion, one nutritionist,* a part-time sociologist who was making other studies in the district, and an office secretary. But soon the volunteers began to come—and to stay—for there was real work for them to do and their various talents were to be used in this citizens' program. Soon 156 were recruited—among them 26 professional nutritionists, home economists, and dietitians.

The first trial was the organization of nutrition classes for the low income groups, but dwindling attendance finally brought the realization that the people were uninterested. They were not applying in their homes the information that the professional volunteers were so painstakingly giving. Lectures and classes apparently were not the proper technic for this group. What would work? What, in the business vernacular of the community organizer, would overcome the sales resistance to nutrition? So nutrition classes were abandoned.

Each group of people to be reached by the program must be carefully analyzed to discover what their special interest in nutrition might be. Only after this special interest was determined, were plans laid. All plans must be designed to capitalize those *special interests*. A separate promotion was developed for each group—and then results came. Department store personnel, railroad men, high school girls and housewives who shopped in the city's public market all had different programs. An evaluation of these programs showed that they had affected the eating and food buying habits of each specific group.

NUTRITION FOR DEPARTMENT STORE PERSONNEL

One of the outstanding successes of the program was the department store

* All educational materials were approved by trained nutritionists.

promotion; so let us look at that project in some detail to see what made it successful. First, what was the special interest of the worker? Second, how was it turned for the benefit of nutrition?

Department store personnel are divided into two classifications: selling and non-selling. The sales girl is much more impressionable, more gregarious too, than her non-selling sister. She is interested in her customers and she admires those who dress nicely. She is "geared to glamor," both in her training and in her thinking. But her non-selling sister behind the scenes, at desks, in fitting rooms, in stockrooms, and in offices, is governed by an entirely different psychology. Usually she is suspicious of ultra-glamor, she admires the plodder, and she goes all out for wholesome sincerity.

Nutrition was sold to approximately 8,000 department store workers at Bloomingdale's, Saks Fifth Avenue, Bonwit Teller, Sterns, and Jay Thorpe by a program cut along lines to fit the psychology detailed above. A single lecture, only 30 minutes in length, plus clever merchandising of nutritious food in some of the employees' cafeterias did the trick. Glamor galore was presented in the lecture for the selling personnel, and wholesome sincerity for the non-seller. It was in stressing the relationship of proper eating habits to the skin, the hair, the nails, and the eyesight that the speaker seemed to ring the bell with the sales girl. By emphasizing nutrition's importance to good eyesight, good health, and high morale, the speaker won the non-seller. In both presentations, volunteer speakers passed along, with conviction and enthusiasm, the basic facts which nutritionists had agreed were essential to good health.

Simultaneously with the lectures, Nutrition Bars were opened in some of the employee cafeterias. Questions at

lectures had revealed other special interests:

"What can I eat to get thin?"

"What can I eat to get fat?"

Immediately those interests were turned to benefit nutrition. "Watch-your-figure" and "builder-upper" trays were offered at the Nutrition Bar. Results were excellent.

Consumption of milk doubled in most stores, and sales of whole grain bread doubled. Consumption of fruit and vegetables jumped 25 per cent in one store, slightly less in the others. At one cafeteria, 8 times as much tomato juice was consumed after the lectures. Everywhere there was a decided decrease in tea and coffee.

AN APPROACH FOR THE RAILROAD MAN

It may well be argued that the glamor presentation is a "natural" for the department store worker; so let us look at the opposite end of the yardstick—the railroad man in his Y.M.C.A. He, too, has his special interest. He is concerned about the fatigue which often sets in before his run is finished, about his arthritis, and his eyesight which is not so keen as it once was.

For this group an evening meeting was planned which combined a nutrition motion picture, "Hidden Hunger," with one of the top-flight volunteer glamor speakers whose enthusiasm for nutrition springs from the fact that proper nutrition helped her through a very serious illness. Skillfully emphasizing some points of the motion picture, such as the sequence dealing with the truck accident due to night blindness, the speaker went on to prove that raw vegetables can be "delicious as well as nutritious." She passed around the audience a huge salad bowl of twelve different raw vegetables, so that sample tastes could be speared out with toothpicks. The bowl came back clean as a whistle, and after the lecture the

question and answer period developed into a lively informal discussion which lasted an hour and a half.

In the Y.M.C.A. cafeteria there was an instantaneous increase in the demand for milk and fruit. The most popular item on the menu was a mixed raw vegetable salad named in honor of the volunteer speaker. Again it was nutrition in relation to the special interest of the railroad man, plus dramatic visual aids, which put the subject over. In other words, "What does it mean to me?"

THE ADOLESCENT GIRL BECOMES INTERESTED IN BETTER NUTRITION

How should one present nutrition to the high school adolescent girl? She is usually thoroughly exposed to nutrition theory in her hygiene, home economics, and health education classes, but only too often she disregards what she has been taught, when left to her own devices to choose her meals. "Nutrition via Hollywood" hits the special interest of the adolescent girl, as proved by an experimental project which the committee undertook in Julia Richman High School, one of the largest schools in the city.

Again a glamor speaker, looking very much as though she had just stepped off a Hollywood set, drew the major part of the assignment. She had just returned from Hollywood where she had wine and dined with the glamor people, and her pockets were crammed with information about what they eat to keep fit for their strenuous work before the camera. The other speaker, beautiful and glamorous, did not have this first hand information; so she fortified herself with wires and letters from favorite stars of the high school girl:

"TELL THE GIRLS AT JULIA RICHMAN HIGH SCHOOL FOR ME THAT THE ROAD TO CHARM

IS ANIMATION, GOOD HEALTH, GOOD LOOKS VIA
FRUIT, VEGETABLES, EGGS AND MILK

DOTTIE LAMOUR"

Six such wires and five letters, all messages to the students from top-flight stars, accented the glamor appeal of the 30 minute assembly lecture. Six assemblies were held to reach the total student body of approximately 5,000 girls. Once again the salad bowl proved itself a powerful visual aid; this time as the "salad bowl act," designed for dramatic audience participation. At each lecture, three volunteers from the student audience came to the stage to be blindfolded by the speaker and to taste the now famous raw vegetable salad. One girl was given a taste of raw spinach, another raw cauliflower, and a third raw broccoli. Signs were held up to inform the audience what vegetable was being tasted and the squeals and laughter which greeted them were electrifying. None of the volunteer tasters could guess correctly what vegetable she had eaten, but all assured the audience that the salad was "perfectly delicious." Obviously the audience was convinced. As soon as the lecture was over there was a surge to the stage and in less than 3 minutes the huge salad was entirely consumed.

Directly outside the assembly hall is the school's large, impressive foyer, and this housed a colorful exhibit put up by the committee. Its theme was "Look Your Best—Feel Your Best—Do Your Best—Through Proper Eating." The well balanced 3 day diet was portrayed in a dramatic manner with menus illustrated through the use of colored vignettes cut from magazines, can labels, and photographs. The morgues of two leading women's magazines and the files of three food canners supplied much of the exhibit material. Photostatic copies of the Hollywood wires and letters were framed on the walls with red tape for all to read. Four

live rats from Cornell Medical College's laboratory, in special exhibit cages, added a dynamic touch to the exhibit. When the properly eating rats, named Julie and Richy for the school, produced quintuplets on the 5th day, nutrition became of added interest to the biology classes and a poem appeared in the school paper commemorating the event. The undernourished rats were dramatic, visible proof to all that an inadequate diet affects the eyesight, stunts the growth, ruins the hair, causes nervousness and listlessness.

Borrowing the successful cafeteria technic from the department store promotion, model trays were made up from the daily menu and these were sold to the students with catchy little word signs, such as "For Charm Specific This Tray Is Terrific," or "Choose This Tray for the Glamor Way." Other colorful signs quoting excerpts from the stars' messages were scattered around the cafeteria walls, additional reminders that proper eating is important to good health, good work, good looks.

Careful planning and timing helped immeasurably in the success of this high school project. The committee's planners met weeks in advance with the home economics chairman of the city's board of education, the principal of Julia Richman High School, and other staff members, including heads of the departments of home economics and health education, and the manager of the school's cafeteria. Details of the plan were perfected in a series of meetings, and when all was ready, the plan was presented to the faculty at one of its monthly meetings. Three weeks later the program opened in the school, and throughout its operation it was backed by excellent support and co-operation from the entire faculty. For three weeks following the assembly lectures, 17 teachers of the health education department concentrated on teaching nutrition from an outline

especially prepared by the Kips Bay-Yorkville committee's professional specialists. Original visual aids, quizzes, and carefully chosen literature were used to supplement the follow-up teaching, which proved to be one of the most important parts of the program.

Again, using a cafeteria base as an observation post, it was determined that results which were secured were substantial. Penny milk is supplied to New York public schools, so milk consumption was limited by the supply available. However, a 66 per cent increase in the consumption of milk was registered in the teachers' cafeteria. Salads, especially mixed green salads which had never been popular with the students, soared into the lead as the most popular food. The demand instantly doubled, climbed steadily until six weeks later four times as many salads were being consumed. With a difficult commodity market in greens at the time, the cafeteria manager could not keep up with the demand of the students. Consumption of whole grain bread doubled. Pastry decreased 25 per cent. Candy, previously the money maker for the cafeteria, decreased 50 per cent. Yet the cafeteria proceeds soared, a daily increase of \$25 overnight, then \$30, and at the end of six weeks \$50.

Radical changes in eating habits proved undeniably that utilization of a special interest was the quickest way to emphasize good nutrition to the adolescent girl so forcefully that she would actually apply the theories to her daily life. Boys, on the other hand, pooh-pooh the glamor approach, for they have a set of special interests peculiarly their own. The air corps, the marines, the army, the navy are all timely pegs, each suggesting endless possibilities for dramatic nutrition promotion for boys. Again, "What does it mean to me?" Baseball is another peg, an ageless special interest for boys.

Sometime a clever nutrition speaker with a flare for showmanship might visit some of the training camps, hob-nob with the baseball men-of-the-year at their training tables, then come back to give the adolescent boys all over America some of the real dynamics of nutrition.

THE HOUSEWIFE CHANGES HER BUYING HABITS

The Kips Bay-Yorkville program was successful in teaching nutrition to the low income groups by the indirect selling method right at the point of sale, whereas it had failed in classroom teaching during the first six months of the program. The committee anticipated that rationing would prove a great boon to nutrition, in fact that it would open wide the door for sound nutrition education, because rationing was the timely special interest of every adult. Therefore, at the request of and with full coöperation of the Department of Markets, the committee opened a Food and Rationing Information Center in a new public market. The formal opening, timed to the distribution of Ration Book No. 2, was ballyhooed sufficiently to make front pages in New York papers, in itself a five-star achievement.

Many community resources made this project possible. New York Hospital loaned a full-time nutritionist for six weeks to train the staff of 20 volunteers, nutrition aides recruited to staff the center in the market. Saks Fifth Avenue sent an ace display man to decorate the seven windows on the street, and an art student painted a 40 foot mural, as a class project, which was hung on the wall above the center. Bloomingdale's department store donated furniture and thoughtfully sent potted plants for the opening. A neighborhood cabinet maker made and donated special display fixtures.

After its widely publicized opening,

the center and its volunteer staff went quietly about its business of nutrition education. Weekly the staff met with the committee's specialists to discuss the problems of the housewife and to receive the latest information available on rationing and nutrition. Staff members were given specialized training in the use of visual aids. Through constant shifting of all displays the consumer was drawn into the center each time she did her marketing to see what was new. Special motion pictures on nutrition, usually with a speaker, were scheduled for Friday and Saturday, the peak shopping days in the market. Mimeographed releases of menus and recipes were passed out regularly, together with carefully chosen literature. Hundreds upon hundreds of questions on rationing and nutrition passed across the volunteers' desk and a careful record of these has been kept. With their constant association with the consumer and their highly specialized training at the hands of the committee's professionals, each member of the center's staff became adept at handling the public.

It is certain that the center does its job well, although this project lacks the cafeteria-like yardstick. One of the district's settlement house directors reported: "The women of our Mothers' Clubs have learned more nutrition from those market windows and interior displays than they did in their classes last winter." That is a real tribute to the effectiveness of the visual aid as a teaching technic. Another community leader said: "The Center in the public market is the finest service offered to the people of our district. We hope it is here to stay."

It is. The center has already celebrated its first anniversary. From the people themselves, many of whom return to the center at least once a week, the volunteers discover that they are learning and applying nutrition prin-

ciples; furthermore, that they have mastered the problems of rationing with their own resourcefulness at substituting the correct foods when scarcities occur or when lack of points forbids favorite items.

The key to the success of this project is a universal special interest—rationing. However, located as it was right at the point of sale, the center took strategic advantage of the rationing program to drive home the principles of good nutrition.

We have made a detailed examination of only four of a dozen or more projects undertaken by the Kips Bay-Yorkville committee. These four projects prove that promotional technics can serve as an excellent plow with which to condition the field for planting. There is no magic formula, other than the fascinating magic of ideas. Nor is the cost prohibitive. Any community can follow the path of the Kips Bay-Yorkville committee. The pattern they applied to nutrition will fit other health programs just as well.

The program ran for 20 months. The actual operating expense for the entire period, including salaries, was less than \$9,000—for a total population of 245,000.

The key to this almost phenomenally low operating cost was the marshalling of all community resources to aid the program. Materials and services were generously donated by advertising agencies, department stores, food stores, chains and manufacturers, by the newspapers, magazines, and radio networks, by the medical school and the college in the district, by the Junior League, the Chamber of Commerce, the Department of Health, the Department of Markets, by the hospitals, the hotels, the churches, and the libraries. To

cite a single example: Original posters and small stickers were needed for the food store promotion. Two advertising agencies within the district created the designs, one of the leading food chains printed the posters on their own presses, while another paid the printer's bill for the stickers. On this job alone the committee spent \$60 of its own money, but received hundreds of dollars worth of promotional material.

In the truest sense, the Kips Bay-Yorkville District Health Committee's nutrition program was a community-wide program made possible by community-wide participation. As such, it may serve as an example to other health programs throughout the country.

CONCLUSIONS

This study of the utilization of business promotion technics in public health education, which was applied to nutrition by the Kips Bay-Yorkville District Health Committee of New York City, demonstrated conclusively that the skillful use of tested business methods can be adapted with great success to the needs of a health education program in a typical American urban area.

But the business man will not stop with promotion. He realizes that promotion has its work to do, but he follows up the promotion with a detailed, carefully laid merchandising plan and uses trained technicians to check the facts he wishes to "sell." This principle can be applied in public health education. But promotion methods, if applied alone, are superficial and will be ineffective. They must be accompanied by a continuing and well balanced educational program.

Gonorrhea Contacts—Criteria for Management*

JAMES H. LADE, M.D., F.A.P.H.A.

*Acting Director, Division of Syphilis Control, State Department of Health,
Albany, N. Y.*

IN the contact reports of the armed forces, civilian health departments have today the richest source of such information in the history of our attempts to control gonorrhea, information which can be utilized as a powerful tool for the eradication of the disease. Since the significance of such an effort depends upon the prevalence of this infection, it may be in order to consider our information on this point.

Although reporting of gonorrhea is required by law, we have no certain assurance that it approaches completeness in any degree comparable to that of syphilis. The follow-up for a case report in syphilis is dependent upon the routine transmission of copies of the serological report to the health department. Even in the present day of selective service examinations, approximately 88 per cent of persons found to have had serologic reactions for syphilis are ultimately reported as cases. It is taken then that syphilis case reports fairly represent the degree to which this disease is diagnosed. But since cultural examination is not indispensable in the uncomplicated case of gonorrhea, and the smear may be examined by the physician himself, no such follow-up of positive laboratory reports has been pursued in this disease. However, it may

be possible to apply our more accurate knowledge of syphilis morbidity to gonorrhea case reporting, in an effort to assay its completeness.

Although only 42,153 case reports of gonorrhea were received in the New York State Department of Health between 1936 and 1942, during which period 105,908 cases of syphilis were reported, it is not felt that this, the usual comparison, is a sound method of estimating the completeness of gonorrhea reporting. Since the Neisserian infection terminates within a period of one year in most cases, either through treatment or spontaneous cure, the number of case reports collected during any year describes the discovery of new cases, while the number of cases of syphilis reported in any year depends upon incidence in past years as well as in the current one. A truer parallel to the number of gonorrhea reports is the number of cases of syphilis of less than one year in duration discovered in a similar period. Though there is an admitted discrepancy in such comparisons in the greater probability of a gonorrhea patient, particularly the male, presenting himself for diagnosis, the number of cases of gonorrhea and early syphilis can be compared with profit if this reservation is kept in mind.

Between 1936 and 1942 inclusive an average of 1,480 case reports for early syphilis were received per year compared with an average of 6,022 gonor-

* Presented before the Epidemiology Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 13, 1943.

rhea case reports pertaining to the same population group. During the last three years of this experience an average of 609 males were reported per year as cases of early syphilis, compared with 4,057 male gonorrhea cases. This ratio, 6.7 times as much gonorrhea as early syphilis among males, compares very favorably with the ratio of syphilis and gonorrhea among the military quartered in upstate New York in recent years, among whom gonorrhea was 4.5 times as prevalent as syphilis. With this relationship in mind, let us review our data concerning gonorrhea reporting.

In 1936 and 1937 approximately 8,000 cases of gonorrhea were reported each year to the Health Department. By 1940 the number had declined to approximately 5,000, from which level there has been no significant variation. Despite the correspondence between the proportions of reported gonorrhea and early syphilis, it is not maintained that the cases reported in upstate New York represent all the gonorrhea occurring in the population, for the number of reported cases of early syphilis are merely a fraction of the number which actually occur—that fraction seen, diagnosed, and reported by physicians. Nevertheless the correspondence between the ratios observed among members of the armed forces and that among New York State civilians suggests that the latter figure may be a reliable indication of the trends of this disease.

It is significant that four of every five cases reported to the New York State Department of Health have been in males. If the number of cases is actually the same in each sex, there were more than 2,800 cases of gonorrhea in women undiagnosed in upstate New York in 1942. This relative infrequency of diagnosis in the female makes for a great reservoir of infection in the population. It is submitted that we cannot hope to control the disease unless these

women are found and treated to the point of noninfectiousness.

But control is hampered at every turn by our difficulty in identifying the infectious case with certainty, particularly in the female. The development of methods of delayed incubation of the gonococcus culture seemed to have been one of the answers to this problem, but it is now apparent that this tool, though a valuable one, does not meet the necessities of a program largely dependent upon the private physician for the following reasons:

1. The culture will not be utilized when the diagnosis of gonorrhea is "ruled out" solely upon the absence of physical signs.
2. The manner of securing specimens must be taught in detail—instruction to which some physicians are not receptive.
3. Patients from whom specimens are taken will sometimes fail to return for therapy.
4. The organism will not be found in an undetermined proportion of actual cases or carriers.
5. The provision of facilities for delayed incubation entails a large overhead expense, even when few specimens are collected.

During these war years we have an unprecedented opportunity to identify and render noninfectious that most important vector of gonorrhea, the promiscuous female with an undiagnosed infection, through the contact reports of the armed forces. But it has sometimes seemed an unprofitable expenditure of time to follow up these reports, find the contact, and guide her to a physician, either in clinic or private practice, only to have treatment withheld because of the absence of signs sufficient to warrant a diagnosis or because the smear or culture was negative. To be sure, some of these women are admittedly free of infection by reason of mechanical or chemical prophylaxis, or simply through errors in securing contact information, but many have subsequently been shown to be infectious cases either through repeated cultural examinations or further con-

tacts with men who subsequently developed evidence of infection within the usual incubation period. After all, so far as contact information is accurate and complete, we have the best evidence of infection obtainable, a positive animal inoculation.

To meet this problem, sulfathiazole is distributed by the New York State Department of Health without requirement of case reports or other identification of the patient. With the drug is included a circular of instruction, advising its use in the female contact as follows:

"Evidence gathered by contact investigation indicates that gonorrhea may exist in a transmissible stage even though physical signs and laboratory tests are negative. Since this situation obtains most frequently in female patients, it is suggested that women who have been in sexual contact with a known case of gonorrhea within one week prior to the onset of his symptoms, or at any time thereafter, receive a full course of treatment when

- "(1) the woman named as a contact admits her exposure;
- "(2) any woman is named by more than one patient in whom diagnoses of gonorrhea have been made;
- "(3) any woman named as a contact has physical findings suggestive of the disease, although laboratory findings are negative.

"It is not suggested that a diagnosis of gonorrhea be made upon these bases, but that treatment is indicated as the safest course of action, in view of the infrequency of reactions to the drug in the recommended dosage."

These criteria are also advised ver-

bally when the contact found by investigation is referred to a local clinic or to her physician. Thus far, these recommendations have been well received by the medical profession. While the culture remains useful in the contact not well identified, and in routine diagnosis, its greatest value is in the determination of the success of therapy. At such a time repeated examinations may be made with less probability of interim transmission of disease than before therapy is initiated.

Though we still have to find the final solution of the gonorrhea problem, it is felt that these simple rules, if widely accepted, can accomplish more toward the reduction of this infection than more cumbersome methods.

SUMMARY

Four of five cases of gonorrhea reported in upstate New York are in males. This suggests a reservoir of undiagnosed and untreated cases in the female.

More intensive case finding measures should be applied to the female population. The contact reports of the armed forces are a valuable index to the infectious female case.

In practice, the gonococcus culture is a cumbersome tool for case finding. Its greatest value is in determining whether therapy has been successful.

A method of influencing the physician to treat the female contacts of known cases of gonorrhea upon epidemiologic evidence only is described.

Proposed Report on the Educational Qualifications of School Physicians*

I. GENERAL SCOPE OF THE FIELD

A. *Specific Contributions to Public Health*

School physicians have always had unique opportunities to improve the health of children and communities. For many years, however, the most important function of the school physician was regarded as the physical examination of pupils. Today he has responsibilities of a much broader nature. Although not responsible for medical care of individual children, his responsibilities do include a thorough knowledge of:

1. The growth and development of normal children
2. Diseases of children
3. The values, methods and limitations of advisory service to parents, teachers, school administrators, and pupils concerning the promotion of optimum growth and development
4. The over-all school program and the types of adjustment which are possible and necessary for health reasons for some children
5. Methods of coördinating the medical and nursing services and other school health work with classroom instruction, physical education and recreation, lunchroom and nutrition services so that he may assist all school personnel to make their most effective contribution to optimum pupil health

6. The facilities available for treatment in the community (chief of which is the private physician)
7. The technics of explaining to the parents, child, and teacher the reasons why good health practices are desirable and why treatment is necessary
8. Individual and community health problems which may be attacked through education
9. The place of the school as an integral part of the community's health resources

These modern functions of the school physician enable him to contribute much more to the health and welfare of children and of the community than did the medical examiner or inspector of past years. They necessitate, however, special educational qualifications over and above the M.D. degree. The purpose of this report is to describe this broadened concept of the school physician's functions and suggest the training and experience necessary.

B. *Future Outlook*

With the increased public attention being given child health, public health and education authorities face greater demands for further development of school health programs. Well qualified medical leadership is essential to sound school health work in both private and public schools.

C. *Number Engaged in this Field*

There are probably well over 5,000 physicians in the United States who give either part-time or full-time service to schools. During the past 25 years the number of full-time physicians in schools has increased considerably.

* The Committee on Professional Education of the American Public Health Association publishes this report before transmittal to the Governing Council in order to permit the members and Fellows of the Association to review it and to offer criticisms and suggestions in the further consideration of the report.

This report, like all other statements of the committee on professional and technical qualifications in public health, is subject to periodic revision in order that it may be kept abreast of the best thought.

D. *By Whom Employed*

School physicians may be employed either by the board of health or the board of education, or jointly by both. In some states the law requires that boards of education employ school physicians. In other places the board of health is legally responsible for school medical work. In some localities the board of education contracts with the local health department for school health work, including the employment of physicians, nurses, and sanitary inspectors. In other localities the school medical director is employed jointly by the board of education and the health department. He may be the director of the bureau of maternal and child health in the health department. In smaller communities the full-time health officer is sometimes designated school medical director.

E. *Promotional Progress*

Opportunities for advancement in this field occur through promotion from subordinate to administrative positions, by moving from smaller to larger school systems, by promotional progress through the health department, and through the growth and expansion of local, state, and national programs.

II. FUNCTIONS OF SCHOOL PHYSICIANS

A. *The Duties and Functions of the School Physician Include:*

1. *Periodic medical examination of children—*

This is to demonstrate the value of health examinations, to give children the educational experience of learning how well they are, to evaluate growth and development, to reveal conditions which might adversely affect the health or educational progress of children, and to furnish recommendations for the care and alleviation of these conditions. Teachers and even parents are often unaware of abnormalities in the child and are frequently unfamiliar with the sources of, and necessity for, treatment. This function necessarily includes

mass-testing procedures such as for vision and hearing.

2. *Professional consultation in health education—*Actually, the pupil's medical examination in the presence of the parents* can be made one of the most potent health education influences in the child's life. These examinations offer the school physician opportunities of presenting health information to pupils and parents, and to confer with teachers regarding individual findings, thus enabling him to influence their ideas on health. Correcting misconceptions, dispelling superstitions, and instilling a desire for accurate, scientific facts are fundamental contributions of physicians to health education.

As a consultant in the preparation of health courses he can check the medical accuracy of study and source materials, suggest timely topics for inclusion, and advise on the selection of health facts important for pupils as distinguished from those of less importance. The 1942 *Year Book* of the American Association of School Administrators states:

"The functions of the modern school physician are educational. The school requires a medical inventory of the health status of its children, both for their general welfare and to indicate necessary variations in school procedures. The health examination, ideally made in the presence of the parents, serves to screen out children where conditions require diagnosis and those whose obvious ill health indicates a need for immediate attention. To the family physician and to available clinics or other approved medical agencies, belongs the responsibility of diagnosis and appropriate treatment. To the school physician and other members of the school staff belongs the responsibility of result-producing health guidance in cases where action is indicated."

3. *Responsibility for the prevention and control of communicable diseases in the school—*Procedures established by the school physician and health officer for preventing the spread of such diseases must be carefully explained to administrators, teachers, custodians, parents, and pupils. Smallpox re-vaccination, diphtheria re-

* Elementary school children are usually best examined in the presence of one or both parents. High school students are often seen individually, and a consultation with parents arranged at a later time.

immunization and such other specific preventive measures as are supplementary to the earlier protection given infants and preschool children and are approved by the local medical profession are systematically organized by the school physician, bearing in mind that these too are potent and beneficial educational experiences. The carrying out of measures in the school for the control of epidemics is often a responsibility delegated to him by the health officer. Guidance in the use of tuberculin testing and other methods of tuberculosis case finding are also the province of the school physician.

4. *School safety and safety education*—This is another part of the school physician's educational function. One of his first responsibilities is the establishment of well understood policies and procedures for the care of school emergencies. The smooth functioning of these procedures when a child is hurt is a valuable piece of safety education for all concerned. His advisory responsibility for the safety of school buildings and grounds, together with his professional knowledge of the results and underlying physical and emotional causes of accidents, make him an invaluable consultant in teaching safety.
5. *Directing teachers and school nurses in systematic and continuous observation of the health of pupils*—so that they may identify those who are normal and so that deviations from normal will be discovered early and investigated by experts. This may include programs for weighing and measuring, for testing vision and hearing, and for securing health histories.
6. *Selecting pupils for special educational programs*—such as lip reading instruction, speech correction, sight conservation, visiting teacher service, modified physical education, shortened school day, rest periods, advising with teachers in constructing educational programs for the physically handicapped. This includes guidance of physical education and corrective physical education teachers in providing modified and suitable exercises for those suffering from postural defects, nervous and crippling disorders and the like.
7. *General supervision of sanitation and other environmental health factors within the school buildings and grounds*—This includes the safety of water, safety of food and milk supplies in the lunchroom and their safe treatment by food handlers, the proper disposal of sewage and wastes, sanitation of drinking fountains and wash

rooms, proper eating, lighting, heating and ventilation, safety of gymnasium and playground.

8. *Medical advice to school authorities on mental and emotional health influences*—such as the length of the school day, extracurricular activities, the frequency of recess periods, type of examinations, methods of marking, and technic of handling individual children.
9. *Professional guidance in the field of teacher's health*—The teacher's mental as well as her physical health is of direct concern to her employer because of its effect on the quality of her work. In this area the school physician is comparable to the medical director of an industry who is given broad responsibility for employees' health maintenance, while actual diagnosis and treatment are usually done by the employee's private physician, the school physician often conducts periodic health examinations and offers consultation to employees with health problems.
10. *Administrative functions*—such as the skilled supervision of personnel within his department, preparation of budgets and reports, the development of health and medical records, and the statistical analysis of records and results.
11. *Responsibility to the school system and the community for integrating the school health program into the public health program of the community**—Health maintenance and protection are of equal importance to infants, children, adults, and aged. The school health program has too often been considered a separate entity, apart from the community health program as a whole. It is a coöperative enterprise both inside and outside the school. Outside the school it involves coöperative effort with health departments, voluntary health agencies, welfare agencies, clinics and hospitals, individual physicians, and organized medicine. Inside the school it involves coöperation between physicians, dentists, nurses, principals, psychologists, cafeteria directors, custodians, classroom teachers, supervisors, and superintendents. The school physician interprets his job to agencies and individuals outside the

* The school administrator is responsible for integrating the activities of the entire school system with the work of many agencies in the community. In his work with community health agencies the school physician is guided by the administrator's general policies and keeps him currently informed.

school. He elicits and fosters the assistance of departments and individuals within the school. He recognizes the interrelationships of all individuals and groups who can help attain the goal of healthier, happier people.

12. *Incidental functions and duties*—which are important but need not be detailed—include coöperation in the development of an effective physical education program on the basis of sound health standards including the health supervision and guidance of athletes; advice to those responsible for the school cafeteria to insure the sanitary safety of food and its nutritional adequacy; assistance with the in-service training of teachers in health subjects; continued search for and elimination of outmoded procedures and policies which impede the securing of medical care and other remedial work; assistance with the vocational guidance of the physically handicapped.

B. *Two Classifications of School Physicians*

There are variations in the responsibilities and duties of school physicians depending in part on the size of the schools served, the number of physicians employed, and the completeness of the school health program. In a large school system there may be many physicians working under the general supervision and direction of a chief physician. In still larger school systems the chief physician may have one or more deputies, some of whom may have special titles, descriptive of their specialized duties. In smaller communities one physician may be employed to serve several school systems. In many areas a part-time physician is used.

To differentiate between the qualifications needed by a physician who administers, or assists with the administration, of a school health program, devoting his full time thereto, and one who works under the supervision of another, two classifications of school physicians are designated for the purpose of this report. They will be referred to here as

"Director, Deputy, or Assistant Director of School Health" and "School Medical Adviser." These titles are not necessarily recommended to school systems, but are used here to differentiate between the qualifications needed for the duties performed by two classes of medical personnel.

1. *Director, Deputy, or Assistant Director of School Health*—Regardless of whether this is his actual title, this type of school physician will ordinarily be a full-time employee of the board of education or the health department, with a rank of, or equivalent to, an assistant superintendent for those employed by schools or assistant health officer or deputy for those employed by health departments. He establishes policies, selects other medical personnel, is responsible to the school superintendent or health officer, or both, supervises, guides, and evaluates all medical phases of the school health program.

Ideally, such a physician with the special qualifications set forth below should be obtained to administer and supervise the medical aspects of the school health program in all schools. This is almost an essential in large communities. In smaller communities a practical solution is for several schools in one or more counties or districts to join in the employment of such a person. In other small communities it is often practical to employ the health officer in this capacity especially if he has the basic qualifications set forth below and has the ability to administer the two positions. This has the advantage of assuring the integration emphasized above.

2. *School Medical Advisers*—Regardless of whether this is his actual title, this type of school physician will be a staff member working under the direction of a "Director of School Health." While good administration will require that the director consult his staff members regarding policies and procedures, "School Medical Advisers" will be concerned primarily with carrying out established procedures. They will ordinarily be part-time physicians. They will be recruited from competent physicians in the community, who wish to devote part of their time to public health, and whose qualifications meet those listed below.

The selection of "School Medical Advisers" should rest with the "Director of School Health" or the health officer if he

is acting in that capacity, subject to such Civil Service or Merit System regulations as may exist. Selections of medical personnel usually calls for careful scrutiny of personal and professional qualifications which is best done by one who is himself well trained in medicine and public health.

III. BROAD EDUCATIONAL BACKGROUND OF SCHOOL PHYSICIANS

Both "Directors of School Health" and "School Medical Advisers" should above all be good doctors. They should have the M.D. degree from a Class A medical school, so designated by the Council on Medical Education and Hospitals of the American Medical Association, plus an internship in a hospital approved by that Council.

IV. GRADUATE EDUCATION

Note: This section proposes desirable areas of competence for physicians engaged in school health work. The recommendations are made for the guidance of (1) officials responsible for the appointment of school physicians, (2) individuals looking forward to careers in school health work, (3) universities contemplating the offering of special courses in this field.

The professional competence of persons now performing creditable service as school physicians is recognized. It is realized that many have not had the opportunity to acquire the formal education or graduate degrees suggested herein. However, it is to be emphasized that an exception to the requirements for a postgraduate course and the other qualifications listed should be made only if the candidate in addition to years of experience has actually demonstrated unusual ability as a school physician.

A. "School Medical Adviser"

A beginning policy of limiting recommendations to those workers who are devoting themselves to a career in full-time public health work has been adopted. The "School Medical Adviser" is not ordinarily a full-time career worker. Recognizing his value to the school health program, however, and the dilemma sometimes confronting school superintendents when local phy-

sicians are recommended for school appointments by influential people, the following suggestions are submitted:

Preference should be given to physicians who have had special training and experience in the fields of pediatrics or internal medicine. Physicians who, in addition to a sound background of clinical experience in pediatrics or internal medicine, have had special training and experience in the field of public health, should receive additional consideration for appointment.

Special training in pediatrics may be judged by possession of one or more of the following qualifications, which are named in the order of their importance: (1) Certification as a pediatrician by the American Board of Pediatrics*; (2) Eligibility for certification by the American Board of Pediatrics, or qualifications meeting Board requirements; (3) Completion of one year as a Resident in Pediatrics in a hospital approved for such residency by the Council on Medical Education and Hospitals of the American Medical Association; (4) Completion of one year on the pediatrics staff of a hospital which has a Resident in Pediatrics and which has been approved for such residency by the Council on Medical Education and Hospitals, American Medical Association; (5) Completion of 18 months' internship, including an appointment in pediatrics in a hospital approved by the Council on Medical Education and Hospitals, American Medical Association; (6) Specializing part-time in pediatrics with an appointment in pediatrics in a hospital approved by the Council on Medical Education and Hospitals, American Medical Association.

* The American Board of Pediatrics is an independent board of pediatricians established to provide a uniform standard of competency in the field of pediatrics. For information regarding these standards, address the Board at 707 Fullerton Avenue, Chicago, Ill.

In larger school systems it is assumed that "School Medical Advisers" will be working under the administrative and supervisory direction of a "Director of School Health." Their training and experience will be augmented by in-service training provided by the director through individual conferences, special studies, group projects, and other supervisory technics.

B. Director, Deputy, or Assistant Director of School Health

1. Specific Knowledge, Skill and Experience—

The scope of modern school health activities requires that the "Director of School Health" be a career man with special training both in education and in public health. In addition to being a well trained physician with some of the qualifications listed above for the "School Medical Adviser" he will need the following special training and experience:

a. Basic principles of public health including general philosophy of mass health protection, epidemiology, vital statistics, record systems and record keeping, environmental sanitation, and the principles of public health administration.

b. Principles of growth and development of the child, the philosophy of modern education and its relationship to other community endeavors, an understanding of school procedures and organization, the principles of educational supervision and administration, educational psychology, the administration of school health programs, including development of health education curricula, the organization and conduct of special classes such as speech correction, lip reading, and sight saving, and the development of school mental hygiene programs including mental testing. Ideally, the "Director of School Health" should be qualified as a "School Medical Adviser" and should have had two or more years' experience in that capacity. Those who do not have the suggested public health and educational background should obtain it as soon as possible after appointment. This should be stipulated at the time of appointment.

c. Upon completion of the "in residence" training listed above, the trainee should have an opportunity for observation

and practice in well selected field training centers where outstanding work is being done. This may require a few weeks to three months depending on the amount of previous practical experience.

These are essentially the requirements for the Master of Public Health degree in most schools.

2. *Personal Qualities*—The need for coöperative effort with many diverse groups and individuals emphasizes the importance of personal qualities of leadership, such as understanding of others, ability to select and help develop subordinates, ability to evaluate and improve accepted procedures, a friendly but dignified manner, a liking for children, and for preventive medicine.

3. *Approximate Time Required for Special Training*—The physician interested in this field presents an educational status somewhat different from the undergraduate or the non-professional student. For this reason, it is believed that one calendar year of specialized, concentrated work, which would include his field work, is sufficient.

4. *Type of Institution Best Fitted for Such Training*—It is important, however, that this work be undertaken in a school where his individual needs are carefully assayed and courses offered to fulfil these needs, where his time is well planned, and where there are rich opportunities for professional association and discussion as well as practice and observation in the field. It is essential that there be close association between the school of public health and the school of education. Neither school alone can complete the training of a potential director of school health. The leading schools of public health in this country and Canada, which have close association with the school of education, particularly those meeting the "minimum facilities needed for graduate instruction in public health"¹ as listed by the Committee on Professional Education, American Public Health Association, are usually well suited to offer this type of training in the time suggested.

1. See "Memorandum Regarding Minimum Educational Facilities for the Postgraduate Education of Those Seeking Careers in Public Health," prepared by the Committee on Professional Education, American Public Health Association and published in the *American Journal of Public Health*, May, 1942.

GEORGE M. WHEATLEY, M.D.

Restrictions on Use of Agar Removed

According to an announcement of the War Production Board, stockpiles of agar have now been improved to such an extent by newly developed domestic production and by imports from Mexico that restrictions on the use of agar have been removed. Beside uses in bacteriological cultures, for which the sea-

weed found on the West Coast is most suitable, agar is also used in the preparation of medicinals and food and in certain manufacturing processes. The WPB has announced that, to insure fulfillment of any emergency needs for agar, a stockpile is being reserved by the Defense Supplies Corporation.

Preliminary Report on a National Program for Medical Care*

AT the last annual meeting of the Committee on Administrative Practice of the American Public Health Association, the committee directed its Subcommittee on Medical Care to draft a set of principles setting forth the desirable content of a comprehensive program of medical care; the methods of its administration; and the part which public health agencies should take in its operation.

In pursuit of this assignment, the subcommittee has completed a tentative draft, which will be considered by the Committee on Administrative Practice at its next meeting, October 1, 1944.

The draft report of the Subcommittee on Medical Care is being published in the *American Journal of Public Health* at this time in order that the entire membership, as well as the Committee on Administrative Practice and the Governing Council of the Association, may have ample opportunity to study the proposals in advance of formal action.

To facilitate the expression of opinion on this preliminary report, the Chairman of the Subcommittee on Medical Care will be pleased to receive and tabulate the viewpoints of members of the Association.

Because of its composition and charge the subcommittee has limited its considerations to one sector of a comprehensive national health program; namely, medical care.

In preparing the preliminary report,

the subcommittee has considered: (A) The objectives of a national program for medical care; (B) The needs for such a program; and (C) Recommendations for immediate action.

A. THE OBJECTIVES

I. A national program for medical care should make available to the entire population, regardless of the financial means of the individual; the family, or the community, all essential preventive, diagnostic, and curative services.

II. Such a program should insure that the services provided be of the highest standard, and that they be rendered under conditions satisfactory both to the public and to the professions.

III. Such a program should include the constant evaluation of practices and the extension of scientific knowledge.

B. THE NEEDS

I. A large portion of the population receives insufficient and inadequate medical care, chiefly because individuals are unable to pay the costs of services when they are needed, or because the services are not available.

II. There are extensive deficiencies in the physical facilities needed to provide reasonably adequate services. Such facilities include hospitals, health centers and laboratories. The needs are most acute in poor communities, in rural areas, and in urban areas where the population has increased rapidly or where the development of facilities has been haphazard or the financial support inadequate.

* Presented to the Committee on Administrative Practice by the Subcommittee on Medical Care as a Statement of Principles.

III. There are extensive deficiencies in the numbers and the distribution of personnel needed to provide the services. Here again, the needs vary according to types of personnel and to types of communities.

IV. There are extensive deficiencies in the number and types of personnel qualified to administer facilities and services.

V. Many communities still are not served by public health departments; others inadequately maintain such departments. Thus, some communities have never utilized organized health work to reduce the burden of illness; and others share its benefits only in part.

VI. Expansion of scientific research is urgently needed. Despite past and current scientific advances, knowledge as to the prevention, control, or cure of many diseases is lacking.

Each of the six conditions defined above can be broken down into many component parts representing specific needs. In general, however, solutions of these broad problems require simultaneous attack on four fronts: namely, the distribution of costs, construction of facilities, training of personnel, and expansion of knowledge.

C. RECOMMENDATIONS

The recommendations presented in this report represent guides to the formulation of a policy for action. It is believed that study of these recommendations by the professions and others concerned in the states and localities will produce new and more specific recommendations for the attainment of the objectives of a national health program.

Recommendation I. The Services

a. A national plan should aim to provide comprehensive services for all the people in all areas of the country. In light of present-day knowledge, the

services should include hospital care, the services of physicians (general practitioners and specialists), supplementary laboratory and diagnostic services, nursing care, essential dental services, and prescribed medicines and appliances. These details of content must remain subject to alteration according to changes in knowledge, practices, and organization of services.

Because of inadequacies in personnel and facilities, this goal cannot be attained at once; but it should be attained within ten years. At the outset, as many of the services as possible should be provided for the nation as a whole, having regard for resources in personnel and facilities in local areas. The scope of service should then be extended as rapidly as possible, accelerated by provisions to insure the training of needed personnel, and the development of facilities and organization.

b. It is imperative that the plan include and emphasize the provision of preventive services for the whole population. Such services include maternity and child hygiene, school health services, control of communicable diseases, special provisions for tuberculosis, venereal diseases, and other preventable diseases, laboratory diagnosis, nutrition, health education, vital records, and other accepted functions of public health agencies, which are now provided for a part of the population.

Recommendation II. Financing the Services

a. Services should be adequately and securely financed through social insurance supplemented by general taxation, or by general taxation alone. Financing through social insurance alone would result in the exclusion of certain economic groups and might possibly exclude certain occupational segments of the population.

b. The services should be financed on a nation-wide basis preferably with

state participation; and under conditions that will permit the federal government to equalize the burdens of cost in accordance with ability to pay.

Recommendation III. Organization and Administration of Services

a. A single responsible agency is a fundamental requisite to effective administration at all levels—federal, state, and local. The public health agencies—federal, state and local—should carry major responsibilities in administering the health services of the future. Because of administrative experience, and accustomed responsibility for a public trust, they are uniquely fitted among public agencies to assume larger responsibilities and to discharge their duties to the public with integrity and skill. The existing public health agencies, as now constituted, may not be ready and may not be suitably constituted and organized, in all cases, to assume all of the administrative tasks implicit in an expanded national health service. Public health officials, however, should be planning to discharge these larger responsibilities, and should be training themselves and their staffs. This preparation should be undertaken now because, when the public comes to consider where administrative responsibilities shall be lodged, it will be influenced in large measure by the readiness for such duties displayed by public health officers and by the initiative they have taken in fitting themselves for the task.

b. The agency authorized to administer such a program should have the advice and counsel of a body representing the professions, other sources of services, and the recipients of services.

c. Private practitioners in each local administrative area should be paid according to the method they prefer, *i.e.*, fee-for-service, capitation, salary, or any combination of these. None of the

methods is perfect; but attention is directed to the fact that fee-for-service has a history of unsatisfactory results.

d. The principle of free choice should be preserved to the population and the professions.

e. State departments of health and other health agencies are urged to initiate studies to determine the logical and practical administrative areas for a national medical care plan.

Recommendation IV. Physical Facilities

a. Preceding, or accompanying, the development of a plan to finance and administer services, a program should be developed for the construction of needed hospitals, health centers and related facilities, including modernization and expansion of existing structures. This program should be based on federal aid to the states and allow for participation by voluntary as well as public agencies. The desirability of combining hospital facilities with the housing of physicians' offices, clinics, and health departments should be stressed.

b. Federal aid to the states should be given on a variable matching basis in accordance with the economic status of each state.

c. Because of its record of experience and accomplishment in this field, the U. S. Public Health Service should administer the construction program at the federal level, in coöperation with the federal agencies responsible for health services and construction.

d. Funds available under this program should be granted only if:

(1) The state administrative agency has surveyed the needs of the state for hospitals, health centers and related facilities, and has drawn up a master plan for the development of the needed facilities (taking account of facilities in adjacent states); or, in the absence of a state plan, the project is consistent

with surveys of construction needs made by the U. S. Public Health Service;

(2) The proposed individual project is consistent with the master plan for the state; its architectural and engineering plans and specifications have been approved by the state agency and/or the U. S. Public Health Service; and there is reasonable assurance of support and maintenance of the project, in accordance with adequate standards.

e. State health departments are urged to conduct studies to develop state plans for the construction of needed hospitals, health centers and related facilities. Such studies should be made in coöperation with official health agencies, with state hospital associations, and other groups having special knowledge or interests.

Recommendation V. Coördination and Organization of Official Health Agencies

a. The activities of the multiple national, state, and local health agencies should be coördinated with the services provided by a national program. There is no functional or administrative justification for dividing human beings or illnesses into many categories to be dealt with by numerous independent administrations. It is difficult to reorganize agencies or to combine activities, and this cannot be accomplished hurriedly. Therefore, studies and conferences should be undertaken without delay in states and communities where the health structure is already unnecessarily complex.

b. The federal and state governments should provide increased grants for the extension of adequate public health organization to all areas in all states. Increased federal grants should be made conditional upon the requirement that public health services of at least a specified minimum content shall be available in all areas of the state.

Recommendation VI. Training and Distribution of Service Personnel

a. Within the resources of the program, financial provisions should be made to assist qualified professional and technical personnel in obtaining postgraduate education and training.

b. The plan should provide for the study of more effective use of auxilliary personnel (such as dental hygienists, nursing aides, and technicians), and should furnish financial assistance for their training and utilization.

c. Professional and financial stimuli should be devised to encourage physicians, dentists, nurses, and others to practise in rural areas. Plans to encourage the rational distribution of personnel, especially physicians, should be developed as quickly as possible, in view of the coming demobilization of the armed forces. Such plans should be integrated with the whole scheme of services and the establishment of more adequate physical facilities.

Recommendation VII. Education and Training of Administrative Personnel

a. Education and training of administrative personnel should be encouraged, financially and technically, especially for those who may serve as administrators of the medical care program, for hospital and health center administrators and for nursing supervisors.

b. State health departments should utilize training funds that are now available to train personnel in such technics as administration of health and medical services, and hospitals. Such a training program may contribute more than any other single activity to the future rôle of the official public health agency. As a corollary, the attention of schools of public health is directed to the importance of establishing the necessary training courses.

Recommendation VIII. Expansion of Research

a. Increased funds should be made available to the U. S. Public Health Service and to other agencies of government (federal, state, and local) for research and for grants-in-aid to non-profit institutions for the support of laboratory, clinical, and administrative studies and demonstrations.

b. The research agencies and those responsible for making grants-in-aid should be assisted by competent professional advisory bodies to insure the wise and efficient use of public funds.

1943 Touches New Low in Infant Mortality

The U. S. Children's Bureau, Washington, announced in July that the lowest infant mortality rate on record, 39.9 infant deaths per 1,000 live births, had been recorded for 1943. According to the Children's Bureau, this drop in infant deaths was doubly remarkable because it was 12 per cent under the 1941 figure and it was accomplished during a war period. According to the Bureau, these declining death rates followed a 7 year trend, the infant mortality rate having been cut almost a third and the maternal death rate more than half from 1936 to 1942. It was pointed out that this marked decline had coincided with the extension of maternal and infant health services by the states, and made possible in

part through the use of Social Security funds. In 1943 the low point in infant deaths also coincided with the implementing of the program under which the wives and babies of service men in the lower-paid grades received free medical care.

In analyzing the 1942 maternal death rate of 25.9 per 10,000 live births, the Children's Bureau pointed out that this figure showed variations among the states from 20 or less in a third of the states to more than 40 in Florida, Georgia, Mississippi, New Mexico, and South Carolina. The Bureau reported however, that remarkable gains have occurred in the southern states, even though the maternal death rate remains comparatively high in these areas.

PUBLIC HEALTH, PUBLIC MEDICAL CARE, AND PUBLIC WELFARE

THERE is a growing tendency for experts in public administration to raise searching questions in regard to the relation between health services and other state and local governmental agencies. "Should the care of the sick poor be transferred from the Department of Charities to the Department of Health?" "Should the Department of Health and the Department of Charities be combined?" "Should the Department of Health and the Department of Welfare be placed under a single administrative authority?" Problems of this sort have become vital issues within recent months—in California, in New England, and at points between.

The administrative reasoning which underlies these queries is obvious. It derives from the general principle that the relative burden of overhead decreases—within limits—with the size of an administrative unit. This principle is sound; but its applicability depends on two important factors—on the meaning of the word "overhead" in a given case, and on the significance of the phrase "within limits."

Certain kinds of overhead are common to many public departments. Accounting and purchasing, for example, involve almost universal problems and can be well handled by central accounting and purchasing services. The major tasks of defining policies, establishing standards of personnel, and supervising and stimulating work, on the other hand, differ widely. Even the most enthusiastic expert on organization charts would not expect to promote efficiency by combining the public library and the fire department. The first essential factor in judging of proposed plans of consolidation is to determine how close is the common bond between two bureaus or divisions whose union is contemplated. From this standpoint, the combination of health and welfare departments has no argument in its favor. It is true that both departments deal with human beings; but, aside from that fact, the spirit, the technics, and the personnel involved are radically diverse.

The health officer and the welfare officer have different trainings and different objectives. They work in widely different, and to some degree alien, psychological atmospheres. The task of the physician is to provide health guidance and health care, in proportion to the need for such care. The task of the social worker is to rehabilitate or to relieve the financial status of families suffering under economic handicaps. These two objectives may be correlated, but cannot wisely be intermingled. Only in the most improbable instances can a man who is competent to direct a health department be competent to direct a welfare department, and vice versa. Under these circumstances, a combination of health and welfare, while it may produce a neater looking organization chart, represents a net loss rather than a net gain in efficiency. Under such a plan, first rate directors of health and of welfare must still be retained; and the result is likely to be merely the addition above them of an additional highly paid political job. Where such a combination has actually been attempted its influence upon the public health service has been almost uniformly damaging.

The transfer of medical service for the indigent or of the management of public hospitals and clinics to the health department is a horse of another color. Here, there is a real community of interest. Here, the health officer has training and experience which fit him—better, at least, than any other public officer usually available—for the management and direction of the services involved.

Many health officers dread such responsibilities and many have refused to accept them—even under considerable local pressure. They feel that the heavy administrative and financial responsibilities involved will divert energies which they prefer to apply to the standard tasks of public health (as has actually happened in certain large American cities). One can sympathize with this very natural point of view and yet feel that it is often a short-sighted one. Where a community is operating a medical care program under the welfare department, or a hospital or tuberculosis sanatorium under a separate governing board, and where there is good reason to believe that these services would operate better under the health officer, the interest of the community must be the governing one. If that interest—in a given case—will be best served, individual preferences and old habits of thought must give way.

At this point, however, we must recall the other qualification of the principle which should govern all consolidations. Increased size of a unit tends to decrease overhead "within limits." Even if two administrative units are of essentially the same kind, there is a maximum size which is economically efficient. In a town of 30,000 population a good health officer can administer both a health department and a hospital, with resulting economy in overhead. In a city of several millions the health department requires every minute of the time of the best administrator who can possibly be obtained; and so does the hospital department. To combine health and hospitals in New York City or Los Angeles County would, again, merely involve an additional high-priced coördinator with no resulting gain. It would sacrifice real efficiency for the sake of an organization chart.

The guide in this matter of consolidation should be common sense, in the light of local conditions and local personalities. "There is no universal truth except that no truth is universal." Good administration must be built round human beings. In general, however, it will be found that consolidation brings good results when—and only when—the things consolidated are of essentially the same kind—and when each of the units consolidated is not quantitatively so large as to demand the full attention of the best executive probably available.

THE BRITISH WHITE PAPER

SOME two years ago, the Beveridge report (which dealt in the main with economic and administrative details of the general social security program) recommended the establishment of a comprehensive national health program for all the people, including all types of medical service. This was one of its proposals which received almost instant approval and was accepted, in principle, by the government in February, 1943. After preliminary conferences with the medical profession, the local hospitals, and local government authorities, a summary of proposals for such a comprehensive national health service has now been prepared and published.¹ It is to be fully discussed in Parliament and elsewhere prior to the introduction of formal legislative proposals.

The National Health Insurance Act² was passed in 1911 and provided general practitioner care for a considerable section of the population. This plan proved so successful that—as early as 1920—a Consultative Council on Medical and Allied Services appointed by the Minister of Health, with Lord Dawson of Penn as chairman, recommended the extension of the program to include all forms of medical service and to reach a larger section of the population. This is the ideal now, at last, specifically outlined in the White paper.

The plan aims at “building on foundations laid by much hard work over many years and making better what is already good.” It involves no compulsion on either medical practitioners or the public but proposes to make available to all people, irrespective of income, not only general practitioner service but consultant, clinic, and hospital services of all kinds. Both individual practice and group practice are contemplated but group practice in local health centers is placed in the forefront of the plan; and it is hoped that these health centers will follow the general lines laid down by the Peckham Center in London.³ It is expected that both voluntary hospitals and local public hospitals will cooperate in the program; and midwifery, home nursing, and health visiting (our public health nursing) will be included.

The cost of the plan—estimated at 148,000,000 pounds a year—“will be borne partly from central funds, partly from local rates, and partly from the contributions of the public under any scheme of social insurance which may be brought into operation.” The program will be operated by local authorities, under the general direction of the Ministry of Health. Both centrally and locally, there will be provision for advisory boards, representing both the public and the professional interests concerned.

The atmosphere of constructive cooperation in which this revolutionary change is being prepared is more significant for us in the United States than the actual program itself. The British Medical Association, at its meeting last fall, advocated the extension of the present National Health Insurance system to include the dependents of insured persons and to cover specialist, laboratory and hospital services; and urged that medical care should be provided by group practice in medical centers. Payment on a fee-for-service or capitation basis, rather than on full-time salary, was favored. The *Lancet* (Sept. 4, 1943) said (in objecting to half-measures), “the public, we believe, will demand that the same medical advantages shall be available to every member of the community, and this is the first requisite for securing the highest quality of service.”

On February 18, the day after the White Paper was released, the British

Medical Association issued a statement⁴ indicating its approval of the general philosophy of the plan and bringing forward a number of specific points on which further detail is required and some on which possibly desirable changes are suggested. The statement concludes with these words: "To sum up, the White Paper provides a framework within which we believe it to be possible to evolve a good comprehensive medical service though its worth to the public and its acceptability to the profession will depend on the clarification and on negotiation on many important points. If the principles with which it opens are the principles which permeate the changes to come, we are hopeful that the profession's full coöperation will be achieved. Our immediate reaction is one of cautious welcome."

In addressing the Royal College of Physicians on March 2, Prime Minister Churchill said, on his side: "It is not a rigid or arbitrary plan. We welcome constructive criticism. We claim the loyal and active aid of the whole medical profession." The program will be submitted for full consideration by all British physicians before action.

There is a similar constructive atmosphere in the discussion of the plan for health insurance now under consideration by the Dominion of Canada.⁵ The Canadian Medical Association has approved the principle of health insurance and has made concrete and helpful suggestions for modification of the measure now under debate.

The problem of the health of the people is too important to be made the football of politics—either governmental or medical. It can only be solved wisely by full coöperation between the public and the professions involved. Why can we not discuss this matter sanely and coöperatively in the United States?

Senator Wagner and his associates in Congress who are studying this problem have repeatedly indicated their eagerness for constructive advice. They have received such advice from the Committee of Physicians for the Improvement of Medical Care and from the Physicians' Forum (which has now spread from New York City to include branches in many other cities). In the main, however, they have been faced only by high-pressure propaganda. Catchwords of "political medicine," "one-man medical care," "Bureaucracy," "doctors—to care for the loved ones—who are first political stooges and henchmen instead of self-respecting human beings"—cannot provide the answer of a great profession dedicated to human service when it is called on for coöperation in working out a program for bringing its benefits to the people at present unable to receive them under self-respecting terms.

The major problem of the next few years is whether the organized medical profession of the United States can find voices more worthy of its vocation than those which now fill the air and inundate the drug stores. In helping to find such voices, the health officer—who is a physician dedicated in special degree to the public interest—can perhaps play a major rôle.

4. Quoted verbatim in the *Social Security Bulletin*, to which reference was made in Footnote 2.
5. See *Canad. Pub. Health J.* for March, 1944 (35, 3:99-108) for statements by the President of the Canadian Medical Association and the Deputy Minister of Health of Manitoba.

BROTHERS-IN-ARMS

WE alluded last month to some of the wider problems involved in building the post-war world.¹ In solving these problems, the experience of the League of Nations will prove of inestimable value. The Health Section of the League (with which we, as health workers, are specially familiar), the International Labor Office, and other technical organizations of the League functioned with a high degree of efficiency; and they are certain, either to be continued, or to be duplicated under another name, in the world order of the future.

One major defect of the League, however, was over-centralization. It has been held by many students of its operation that the evolution of regional organizations within a broader international framework should be an essential factor in our plans for the future.

In this area of experimentation in international planning we, in the Americas, have an excellent model in the Pan American Sanitary Bureau. For the past two years, most of the American republics have been bound together in alliance against our foes in Germany and Japan. Since 1902, however, we have been associated in a continuing program of defense against the common enemies of mankind, the causes of preventable disease and death. The marble building of the Pan American Sanitary Bureau in Washington is an impressive symbol of a united purpose.

The cause of coöperation in the war against disease in the Americas has received powerful stimulation during the past two years through the activities of the Inter-American Cooperative Health Services of the Office of the Coordinator of Inter-American Affairs. Major General Dunham² has described some of the accomplishments of this organization, in close coöperation with the Pan American Sanitary Bureau and other United States agencies, and with the health authorities of 18 countries south of the Rio Grande.

It is an inspiring story; of health centers in El Salvador, of the sanitation of rubber plantations and railway construction in Brazil, of nutrition in Colombia, of malaria control in Honduras. It involves the training at our schools of public health of hundreds of young men who will go back to their countries and bring forth fruit an hundredfold. It includes emphasis on such fields as public health nursing, social service, and popular health instruction, in which we, in the United States, have been able to play a special pioneering rôle.

The really significant thing about this problem, however, is its truly coöperative nature. Of the men and women actually at work on projects sponsored by the Coördinator, on January first, 200 were from the United States, and 13,000 from the nations in which the work was carried on. More and more, in the future, the plan will operate as a two-way process. The heads of the schools of public health in Mexico and in South America who visited the United States last fall revealed to us a wealth of opportunity for students from the United States. We shall want to study malaria control in Brazil and social security in Chile and epidemiology in Peru. The tradition of Gorgas and Reed and Theobald Smith—of Carrion and Chagas and Oswaldo Cruz and Carlos Finlay—is a common tradition for us all. We shall more and more fully coöperate, as brothers-in-arms against all those evils, in the physical environment and in the social environment of man, which menace the health of the American peoples.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted.

The March of Medicine: Number VIII of the New York Academy of Medicine Lectures to the Laity. New York: Columbia University Press, 1943. 158 pp. Price, \$2.00.

There has never been a time when the work of the physician was of greater interest—or of greater importance—than it is today. Under the impetus of war, medical research has been greatly accelerated and new discoveries and theories are almost daily in the news. Unfortunately, however, developments in the medical field have been so numerous and rapid that the average layman is at a loss to keep up with them or to appreciate fully their implications. Now, as never before, the average man in the street wants to know what our doctors are doing, what they are thinking, what plans they are offering for a healthier, saner post-war world. In its 1943 *Lectures to the Laity*, published under the title "The March of Medicine," the New York Academy of Medicine has taken an important step toward meeting this need. Here are six provocative discussions by eminent leaders in the field of medicine and psychiatry discussions of such widely varying and important topics as the rehabilitation of our criminals, the effect of war on medicine (and vice-versa), the basic requirement for post-war peace, and a new approach to the problem of teaching. Each of the lecturers brings to his or her subject the experience of years of studying and working with human beings, plus the discipline natural to scientific workers. As a result, their thoughts are, for the most part, intensely practical and down-to-earth.

Dr. Bernard Glueck's discussion of "Crime and Punishment" offers an unusually clear presentation of the new trends in the rehabilitation of our law-breakers, and of the great need for making the punishment *fit the criminal*. In the lecture entitled "The Scientific Method and Our Plans for Peace," Sir Norman Angell makes a brilliant plea for collective security as the only possible basis for avoiding aggression in the post-war world. Another specially interesting contribution is that of Dr. Franz Alexander, which analyzes and refutes the age-old argument that wars are the inevitable outcome of man's innate aggressiveness. Into his lecture on war and medicine, Dr. Edgar Erskine Hume packs a great deal of historical information on the importance of war to the progress of medicine—as well as on the rôle of disease in the campaigns of the past. The remaining two topics dealing respectively with the implications of a child's concurrent physical and intellectual development and the ways in which natural law affects man's progress also provide much food for thought.

If there is any one criticism which might be leveled at the Academy of Medicine's *Lectures to the Laity* for 1943, it is that they are not sufficiently colloquial. Several of the discussions abound in such terms "palmar aponeurosis," "subcutaneous tenotomy," "dialysis," and "pyrophosphoric esters" a vocabulary which actually helps defeat the purpose of the volume by making difficult, if not baffling, reading for the layman. Despite this sometimes frightening terminology, however, *The March of Medicine* still

makes stimulating reading and is setting a valuable precedent in bringing to the public the challenging thoughts and opinions of some of our medical leaders.

SAVEL ZIMAND

Encyclopedia of Child Guidance
—*Edited by Ralph B. Winn. New York: The Philosophical Library, 1943. 456 pp. Price, \$7.50.*

This book contains summaries of knowledge about diverse material in the field of child guidance, especially that related to normal and pathological behavior of infants and children, psychological mechanisms, psychological testing, education, physical and emotional development, relationships between individuals, and physical defects. As the editor points out in the preface, the book has omissions in topic and material; to this reviewer the omissions are so many and so great that the book is not a standard reference book and its value as an encyclopedia of child guidance is therefore greatly lessened.

Most of the items are presented simply and clearly so that they may be easily understood and applied by workers in fields other than child guidance, and the discussions are frequently followed by good bibliographies and include those of antithetical thought. On the other hand, there is an unfortunate lack of bibliography for certain items; for example, the consideration of "castration complex" does not carry with it any bibliographical reference.

It is unfortunate that among the fifty or more contributors there is a predominance of educators and psychologists and that the profession of medicine, especially psychiatry, is inadequately represented. Familiar names of physicians doing basic work in the field of child guidance are lacking, and although psychoanalytic material is included in the summaries, there is a deficiency among the list of contributors of outstanding psychoanalysts.

In format the book at first glance appears attractive and weighty but on closer examination one is surprised at its poor construction. This may, however, be a wartime defect. All in all the cost seems excessive.

MILTON J. E. SENN

Cancer Teaching Day—Division of Cancer Control, New York State Department of Health, Albany, N. Y., Vol. III, 1943. 66 pp.

All persons interested in the medical aspects of cancer control will find value in this publication of the New York State Department of Health summarizing the medical clinics in Binghamton, Rochester, and Utica. The volume includes brief addresses by six qualified practitioners on The Management of the Patient with Incurable Cancer; What May Be Logically Expected from Pre and Post Operative Radiation in Mammary Cancer; The Diagnosis and Treatment of Cancer of the Prostate; The Role of the General Practitioner in the Cure of Cancer; The Significance of Enlarged Lymph Nodes; and The Importance of Pathologists in the Cancer Program.

This volume is the third in a series representing addresses before groups of the county and district medical societies of New York State in coöperation with the University of Rochester School of Medicine and Dentistry, the Medical Society of the State of New York and the Division of Cancer Control of the New York State Department of Health.

REGINALD M. ATWATER

Rorschach's Test, I. Basic Processes—By Samuel J. Beck, Ph.D. New York: Grune & Stratton, 1944. 223 pp. Price, \$3.50.

Although this book is intended primarily for the use of those persons who either are aspiring to become or have already become experts in the Rorschach method, it will have a cer-

tain amount of interest for persons who have come into contact with the test as a result of its increased utilization by those who are professionally concerned with normal and abnormal personality. In essence the book is a manual of rules for classifying the responses to the Rorschach ink blot figures in accordance with Rorschach's terminology. It does not go beyond this basic step into the interpretation of these responses—a task which will be undertaken in a forthcoming volume. Each chapter deals with a separate aspect of the scoring process and the various underlying principles are clarified by the presentation of thousands of responses which have been classified by the author. The realization of the contention of the large group of Rorschach specialists that the technic is essentially an objective, scientific method will certainly depend upon the general adoption of some explicit system of scoring such as this book describes.

LILLIAN DICK LONG

Atlas of the Mouth—By Maury Massler, D.D.S., M.S., and Isaac Schour, D.D.S., Ph.D., D.Sc. Chicago: American Dental Association, 1944. 104 pp. Price, \$2.50.

Here is substantiation of the saying "One picture is worth a thousand words." With unusually graphic illustrations and a minimum of textual explanations, the authors and their assisting artist present a concise review of oral anatomy and pathology that is so excellent that it is difficult to temper one's enthusiastic endorsement of it.

Dentists and physicians will find it an extremely valuable reference work through which both the possibly forgotten facts of oral anatomy and the more recent knowledge of oral pathology or abnormalities may be quickly reviewed. The text, technical, of course, in its terminology, is marvelously concise. Indeed one is inclined

to feel that, in some instances, the authors have adhered too strictly to their obvious intention to limit their written words. However, even this criticism is scarcely valid since, according to the authors, the book is intended primarily to cover subjects "of common interest to both the dentist and physician" and to "stimulate the reader to seek further information." As the authors also point out, the comprehensive scope of the *Atlas* makes inadvisable an exhaustive treatment of any one of the numerous subjects depicted and briefly discussed. The omission of a topical index, whether for the sake of brevity or not, is regrettable.

Together with the authors, the Council on Dental Health and the Bureau of Public Relations of the American Dental Association are to be complimented for their respective parts in presenting an extremely worth while book to the health professions.

RICHARD C. LEONARD

Costs of Dental Care for Adults, Under Specific Clinical Conditions—By Dorothy Fahs Beck, assisted by Mary Frost Jessup. (2nd ed.) Sponsored by the American College of Dentists. Lancaster, Pa.: Lancaster Press, 1943. 306 pp. Price, \$1.50.

This report is a continuation of a series of studies on the economic and social aspects of dental practice, the first of which was published in 1929. The author contributed one of these, "The Cost of Equipping a Dental Office," in 1932. All were prepared and published under the auspices of the American College of Dentists. The latest report was referred for comment and criticism to more than forty members of the College before it was published. It should reflect the opinions of this organization.

This particular study is limited to the "twin questions of time and cost" in rendering adequate dental service to a

low income group of patients; i.e., the *time* required to provide initial rehabilitation service and maintenance service thereafter and the *cost* of such services over a period of years.

The records of several clinics were used to secure necessary data, the principal one being the Dental Health Service Clinic in New York City, which had been operating as a pay clinic for a low income group for twelve years. The analysis of the records of this clinic was thorough and exhaustive. The Board of Directors of this clinic is made up of well known dentists in that community, who cooperated fully in the investigation. The investigators, however, admit that the clientele of this clinic "is not strictly representative of the low income group" and that the records of only 485 of the 21,281 patients treated at the clinic during the twelve years of its existence qualified for the sample. This represents 2.2 per cent of all registered patients.

The authors assume that these data will be of value to the dental profession, charitable institutions, and departments of public health. The profession, as a rule, seeks its clientele from the higher rather than the low income groups and is not particularly interested; the charitable institutions include dental care as one of their benevolent functions; the report is of value to them. Departments of health are primarily concerned with the prevention of disease rather than its cure, except where the latter is imposed upon them by law, regulation, or other official authority. It is doubtful whether they will find much of value in the report.

Without question, the largest expenditures of public funds for dental care and dental health education are applied through public schools and departments of health toward the prevention or control of dental disease in

children, which is an indication of public interest in dentistry. This objective will never be attained by filling teeth and replacing those that are lost.

GUY S. MILLBERRY

The Art and Science of Nutrition
—By *Estelle E. Hawley, Ph.D., and Grace Carden, B.S. (2nd ed.)* St. Louis: Mosby, 1944. 668 pp. Price, \$3.75.

In revising their valuable book to produce this second edition the authors have managed to avoid expanding the volume more than about fifty pages. There are the usual numerous illustrations characteristic of the original volume; of the total of 139, 11 are in colors. Additional topics found to have received some discussion are food fads and geriatrics.

Any book that aims to cover as much ground as this one must necessarily limit sharply its discussion of individual topics. As illustrations of what this means here consider that the entire description of all the vitamins is accomplished in 36 pages; magnesium is covered in ten lines and manganese in 5 lines; and no mention made anywhere (so far as this reviewer could find) of balance studies with these mineral nutrients made on human beings. Perhaps this is not serious for the circle of readers for whom the book is intended, namely people who would not understand very much of the scientific details if they were given.

This reviewer believes that the authors might well have clarified the meaning of the term "gamma" (pp. 140-141), which is merely a Greek letter used by some workers and publishers as the symbol of the microgram, a unit of weight with which many vitamins are measured. It seems unfortunate that the official spelling of the name for vitamin B₁, namely *thiamine*, has not been used, especially since the spelling with a final *e* has been made

official by the United States Pharmacopoeia, the Federal Food and Drug Administration, two Councils of the American Medical Association, and other organizations of specialists that might be mentioned. On page 195 appears a short discussion of food laws, and the only federal law referred to is the one passed in 1906 in response to the agitation by Dr. Wiley. It was certainly an oversight to fail to mention the Federal Food, Drug and Cosmetic Act passed on June 25, 1938.

Mention of these minor imperfections should not, however, blind us to the real merits of this book. It contains a wealth of information, is full of useful tables and practical suggestions for meeting important dietary problems, is readable, full of pictures, and in every way a most valuable volume for the average reader. The reader who has had some training in nutrition will doubtless desire more detail than this book furnishes, but even he should find the illustrations and tables useful.

GEORGE R. COWGILL

Births, Infant Mortality, Maternal Mortality—Graphic presentation, 1940. Washington: U. S. Department of Labor, Children's Bureau, 1943. 34 pp. Price, \$1.00.

This pamphlet, containing 34 tables and the same number of full page charts, presents the more pertinent facts on births and on infant and maternal mortality in the entire country and in individual states, with subdivision according to color. Because of differences in the definition and criteria of a stillbirth employed in the several states, a discussion of this subject is limited to an illustrated tabulation of these differences.

The charts are well arranged and clearly drawn. The graph on page 13B, depicting infant mortality in the expanding Birth Registration Area in 1915-1940, would gain by the addition of

rates between one day and one month. The comparison made between the mortality under one day and the total mortality under one month obscures the very important fact that in the twenty-five year interval the rate between one day and one month was cut in half, while that under one day remained practically unchanged.

Since the foreword devotes about one-third of a page to a discussion of the semilogarithmic scale, the pamphlet, clearly, is not intended for professional vital statisticians. It is therefore regrettable that the reader is not told about the effect of under-registration, especially of births, upon the comparability of the rates. For instance, the table on page 11A tells us that in 1940 the State of Oregon had the lowest infant mortality rate, 32.9, while Arkansas was twenty-fifth with a rate of 45.7. However, according to a study made by the Bureau of the Census in 1940, only 76 per cent of the births were registered in Arkansas as compared with 97 per cent in Oregon. Arkansas could reduce its recorded infant mortality rate to 35.7, rising to the fifth place now occupied by Nebraska and Washington, through the mechanical expedient of lifting its birth registration to the Oregon level.

J. V. DEPORTE

Your Eyes—By Sidney A. Fox, M.D. New York: Knopf, 1944. 191 pp. Price, \$2.75.

In this very timely book, the author, in a note to the reader tells better than anyone else could his reasons for writing it. "The average man," he says, "knows so little about his eyes! . . . offhand I can think of nothing of as great immediate importance to man about which he knows less. . . . Much of the little that the average man knows about his eyes is hearsay. Often it is misinformation gleaned from sources more interested in selling a product

than in disseminating accurate facts. The patient is entitled to more than this . . . judging from questions constantly asked in office and clinic. I have attempted to answer some of these questions."

In fulfillment, Dr. Fox has translated the terms used by the ophthalmologist into everyday language for the layman who is sufficiently interested to want to know what his eye difficulty is (if he has one), its cause, what can be done about it and, in particular, how it might have been prevented. It is evident that from his experience as an instructor of ophthalmology in the School of Medicine of New York University (Dr. Fox is now a major in the Medical Corps of the Army of the United States) he realizes that to be of value material must be presented in a form that can be assimilated by the learner. He presupposes that readers who are sufficiently intelligent to ask pertinent questions are entitled to answers that will not only give them the needed information, but increase their desire to know more and so gain their coöperation.

For those interested in the historical development, the first chapter, "The Light of the Body," will prove an excellent introduction to the material that follows. The chapter on "How We See" will clarify many misconceptions. Considerable space is devoted to the eyes of the young, those of the adult, and those of advanced years. In all cases emphasis is laid on early and adequate attention to any deviations from the normal. This is especially noted in the chapter on eye muscles. The author states that a cross-eye in an older child or adult is usually the "hallmark of neglectful careless parents." "Nowhere," he says, "is the biblical phrase about the sins of the parents visited on the offspring more applicable . . . the sins of omission." Dr. Fox warns of the necessity for

caring for those latent muscle difficulties called phorias that "lie in wait ready to pounce and destroy our comfort."

Evidently some of his patients have been rebellious to the idea of wearing glasses. As an antidote he suggests it might be well that they ask themselves the question, "Would you rather that eyeglasses had not been invented?"

Color vision, so important a factor in wartime, is discussed, and the part that illumination plays in the intricate process of seeing is presented. A chapter devoted to eyes in traffic brings home the responsibility of both drivers and pedestrians if accidents are to be prevented.

Dr. Fox warns that quacks and high-powered salesmen, capitalizing on the fear of the populace, recommend panaceas for every ill that are all too often accepted by the credulous. He gives many practical helps and suggestions in his chapter on hygiene and first aid, emphasizing however, that sound advice is necessary before starting "on the uncharted sea of self-medication." He dwells on the necessity for immediate attention by qualified persons to eye injuries.

A few illustrations and line drawings help to clarify some of the more difficult points. A comprehensive index facilitates the ready finding of information on particular phases of the subject.

That noted ophthalmologist, Dr. Webb William Weeks, a former teacher of Dr. Fox, to whose memory the book is dedicated, would indeed, as the author states, "have smiled quietly and approved."

WINIFRED HATHAWAY

Course of Study in Health.
Grades One to Eight—*Prepared by the Boston Health Department and the Schools of the Archdiocese of Boston.*
Boston, Mass., 1943. 172 pp.

This bulletin is a unique contribu-

tion in the field of school health education. Its significance lies not so much in its detailed content, as useful and practical as the content is, but in the manner in which the bulletin was developed. Working under the direction of a Central Advisory Committee, made up of representatives from the Boston Health Department and the Archdiocese of Boston, health educators of the department and experienced teachers in the parochial schools collaborated in the preparation of this material.

The stated purpose of the program as outlined in the bulletin is "to motivate and coordinate the activities of all who are engaged in caring for the health of children in the Parochial Schools of the City of Boston. . . . It not only seeks to keep children healthy, but it also emphasizes the educational values that must be an important feature of a sound and progressive school health program."

An Introduction outlines health education objectives and defines terms commonly used in school health. This is followed by a section on Health Education through Health Services, Physical Education and Healthful School Living and one on Health Education through Routine Procedures. In both sections policies and procedures applicable to this particular school system are well defined. The bulk of the bulletin is devoted to specific and detailed outlines for teaching health by direct instruction. Curriculum content and units are suggested for each grade, with an attempt at progression to make possible new material and new perspective from year to year. A health habit check list is provided in order that each teacher may determine the specific health problems of her school, and direct the health teaching for the year along channels that will be practical and suited to pupil needs.

The units contain a rich source of

teaching suggestions and pupil activities. Each unit includes suggestions for correlations with other subjects as well as sample test questions. At the end of the bulletin one finds an extensive list of sources of health education material which should be of great help to the busy teacher.

A course of study is most useful when it stems from experiences of teachers and pupils themselves, and when it embodies the philosophy of the system for which it is intended. This course of study does both, and serves as a splendid example of an approach in curriculum building which could be followed by other school and health groups.

RUTH E. GROUT

The Compleat Pediatrician—By W. C. Davison. (4th ed.) Durham, N. C.: Duke University Press, 1943. 270 pp. Price, \$3.75.

The appearance of a fourth edition of this unusual work testifies to substantial popular appeal. The new edition appears to be considerably larger than the third and contains much new material. The arrangement, numbering of the articles, and extensive cross referencing are unchanged, and the author still discusses "the 329 diseases to which children are heir."

In order to make the book practical "it is as brief and concise as possible, and pathological and physiological explanations . . . are omitted." This inevitably tends to dogmatism and has resulted in some rather amusing sentences. One quotation will be of particular interest to public health workers. Under the general heading "Growth, Development and Child Care" appears the following:

"Sex: The ratio of males to females at birth is 1,043 to 1,000, and is higher in rural areas, immediately after wars and in Greece."

Inclusion of extensive factual material, details of laboratory tests, pre-

scriptions and much tabular matter undoubtedly makes the book very useful to pediatricians like the author, who says that rarely a day passes without his having to consult the book. But the author's training and background give him a critical ability which the average reader does not possess. There would seem to be a real danger that an uncritical reader might be misled by the many sweepingly dogmatic statements which the book contains.

Among the favorable items may be noted a very considerable emphasis on prevention, including health supervision and child guidance, typified by the statement in the introduction—"More children are saved by preventing disease than by treatment."

MYRON E. WEGMAN

The Illinois Commission for Handicapped Children—*Its Organization and Function*. 1943. 3 pp.

Children with Cerebral Palsy, 1943. 31 pp.

The Epileptic Child in Illinois, 1943. 40 pp.

Children with Speech Defects, 1943. 24 pp.

The Educable Mentally Handicapped Child in Illinois, 1943. 46 pp.

The Illinois Commission for Handicapped Children, Chicago, has released the above pamphlets which should be successful in stimulating local and general interest in the needs of children with certain specific restrictions.

The first pamphlet briefly describes the organization, duties, and responsibilities of the Commission as the official state agency created in 1941.

Children with Cerebral Palsy concisely describes the problem, enumerates present provisions in Illinois for care and education, and makes specific recommendations for a state-wide program. Of interest is the proposal to

establish a demonstration center which, in addition to providing necessary care for children with cerebral palsy, would provide opportunity to study technics to assist such children and would provide training facilities for specialized personnel.

The general apathy concerning persons suffering from convulsive seizures, whose condition is not so serious as to require custodial care, is brought out in *The Epileptic Child in Illinois*. Again, the problem is adroitly presented. Facilities and unmet needs in the state are described. A state program for children with convulsive seizures is proposed and specific recommendations are made. In the opinion of the Commission, a program involves three major phases: (1) treatment, (2) public education, (3) research. Insufficient emphasis is placed in the pamphlet on the importance of necessary study by currently accepted methods by qualified personnel to assure an accurate diagnosis and indicated therapy.

Children with Speech Defects follows the general pattern of the two preceding ones. Included are the suggestions that the state teachers' training colleges be the centers for speech clinics and that a basic speech course be part of the training specified for state certification.

The Educable Mentally Handicapped Child in Illinois concisely presents recommendations to improve services and facilities for these children with emphasis on centralized administration and on extensive and coördinated plans for vocational education, guidance, training, and placement with follow-up care and supervision.

These pamphlets should be of interest to all individuals concerned in public health activities.

GEORGE S. FRAUENBERGER

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Something to Crow About—

As this fine report appears in a publication which you may not see, an abstract of it is attempted here—contrary to custom. Cancer patients are seeking medical care with only an average delay of 3 months after noticing the first sign: this is earlier than ever before in Massachusetts's history. As a measure of the effectiveness of early care, the records show that 80 per cent of patients with skin cancer and nearly 40 per cent of other cancer patients who were treated during the first month are alive 10 years later. This is twice the survival rate when care is delayed more than 1 month. Ten per cent of the state's cancer patients were cared for in public clinics and a significant improvement is noted in the proportion of the patients who are seen early. The cancer death rate has declined steadily during the past 9 years. Local cancer committees have carried on effective life saving educational campaigns.

ANON. Cancer Toll in Massachusetts Cut by Education. *Bulletin* (Massachusetts Dept. of P. H.). 9, 3:42 (June), 1944.

About Help That You May Someday Need—Eight objectives in health education as currently undertaken by the U. S. Public Health Service are outlined in this useful paper read before the last meeting of the A.P.H.A.

P. S. Dr. Studebaker's paper about School Health Education programs, which accompanies Dr. Coffey's statement, also should not be missed.

COFFEY, E. R. Planning for Health Education in the War and Post-War Periods—the National Program. *Pub. Health Rep.* 59, 28:897 (July 14), 1944.

Administration by Experts—

By long odds, the paper-of-the-month is this brilliant essay. If you will insert the word "health" between the words "public administration" wherever they appear, then the President of Princeton will be talking directly to you. Here is only one of the many quotable gems in it: "No profession is competent to decide the problems arising from its relation to other groups and society." Hurry to the nearest library for this issue. Better still, subscribe to the *Quarterly*; it is by far the most provocative journal in our field.

DODDS, H. W. The Rôle of the Expert in Government: His Use and Abuse. *Milbank Quart.* 22, 3:207 (July), 1944.

When Appetites Were Gargantuan—Excellent source material for your possible comment on eating habits in "the good old days" is this combing of the literature of an earlier time.

FLYNN, M. A. Dining with Samuel Pepys in Seventeenth Century England. *J. Am. Dietet. A.* 20, 7:434 (July-Aug.), 1944.

In Sweden, Too—Swedish anti-venereal disease laws, long held up to the world as models of enlightened control measures, did in fact produce gratifying results during the 20's and 30's. In 1940, the gonorrhea rate, thanks to improved diagnostic and therapeutic methods, dropped to its lowest reported figure. But wartime conditions have changed this happy state and both syphilis and gonorrhea have soared to new heights. How the Royal Medical Board proposes to meet the new conditions will interest American V.-D. officers.

HALLGREN, R. J. M. Legislative Measures

against the Spread of Venereal Diseases in Sweden. *Pub. Health.* 57, 9:96 (June), 1944.

Of Interest to Maternal Hygienists—Threatened abortion occurs in 1 out of every 8 pregnancies and three-fifths of the women so threatened will abort if the condition goes untreated. Spontaneous abortion occurs in 1 of every ten pregnancies. The modern, hormone-vitamin treatment of threatened abortion is discussed. It will do you no harm to know about this paper even if your particular job is plumbing inspection.

HERTIG, A. T., and LIVINGSTONE, R. G. Spontaneous, Threatened and Habitual Abortion: Their Pathogenesis and Treatment. *New Eng. J. Med.* 230, 26:797 (June 29), 1944.

Underscoring the Health in Public Health Nursing—It seems this fellow went out on the street and asked a lot of people what they thought about the public health nurse. What he learned induced him to ask the nurses if they were doing all they should to sell themselves to the public. There is no good reason why this wholesome paper should be read only by nurses. "It tolls for thee," too.

HUGHES, H. H. The Nurse in Public Relations. *Pub. Health Nurs.* 36, 7:318 (July), 1944.

Another Case of the Ounce vs. the Pound—Ringworm of the scalp, it is alleged, is frequently found in many large cities in addition to New York, where several thousand children have been infected, the epidemic spreading for more than a year. Ultra-violet rays are used in case finding and x-ray in therapy. Communities now free of this disagreeable visitor are urged to adopt preventive measures.

LEWIS, G. M., *et al.* Measures to Prevent and Control an Epidemic of Ringworm of the Scalp. *New York State J. Med.*, 44, 12:1327 (June 15), 1944.

Concerning Public Relations—Addressed particularly to water works operators this admonition to let staff members really know what is going on, might well have been broadened to include all public health administrators. Even with small staffs an employee publication is suggested—not necessarily a slick paper brochure, for a mimeographed sheet can do the job as well. It is what goes into the news letter that counts.

MCDONNELL, E. Does the Team Know the Score? *J. Am. Water Works A.* 36, 7:777 (July), 1944.

Anent Coffin Nails—Using ordinarily healthy smokers, these researchers found that smoking two standard cigarettes increased basal metabolic rates, speeded up heart action, and affected the electrocardiographic picture. Injecting 2 mg. of nicotin had the same effect but smoking corn-silk cigarettes did not. It is not likely that these findings will have any effect on your habits, but you should read the paper.

ROTH, G. M., *et al.* The Effect of Smoking Cigarettes. *J.A.M.A.*, 125, 11:761 (July 15), 1944.

Ill-Wind Department — Maternal hygienists will be interested in these conclusions: patients allowed out of bed 3 or 4 days postpartum feel stronger and better able to resume routine duties than do those kept in bed the usual 12 days. Involution of the uterus was accelerated, no phlebitis occurred and there were no complications due to the early rising.

ROSTEIN, M. L. Getting Patients Out of Bed Early in the Puerperium. *J.A.M.A.* 125, 12:838 (July 22), 1944.

An Apple a Day—Four papers that you should not miss are these on the state of our physical fitness, based upon experience in the examination of 13 million young Americans called for the

army, the examination of high school students for the Victory Corps, and on work with industrial employees. It would seem that national fitness is a project in which all health workers might make a contribution, so it is a pleasure to find prominent members of the A.P.H.A. among the writers and discussants in this symposium.

ROWNTREE, L. G. National Program for Physical Fitness (and three related papers). J.A.M.A. 125, 12 821 (July 22), 1944.

Midges Are the Vectors—If you are intent upon keeping up with all the weird variety of tropical infections which returned soldiers will bring to your community, you may want to refresh your knowledge of phlebotomus fever. If you do, this paper, with its all-inclusive title, seems to be an excellent medium for that purpose.

SABIN, A. B., *et al.* Phlebotomus (Papataci or Sandfly) Fever: A Disease of Military Importance, Summary of Existing

Knowledge and a Preliminary Report of Original Investigations. J.A.M.A. 125, 9:603 (July 1), 1944.

More Good Penicillin News—Six of eight ophthalmia neonatorum patients treated with penicillin showed pronounced clinical improvement within 24 hours and complete recovery in from 3 to 6 days.

SIEVERS, J. J., *et al.* Penicillin in the Treatment of Ophthalmia Neonatorum. J.A.M.A. 125, 10:690 (July 8), 1944.

The Stork Was Busy—During the first war year more babies were born in these United States than ever before and maternal deaths, infant deaths, and stillbirths were at their lowest. If that introductory statement doesn't send you to this excellent summary, then your statistical soul must be dead.

YERUSHALMY, J. Births, Infant Mortality, and Maternal Mortality in the United States—1942. Pub. Health Rep. 59, 25:797 (June 23), 1944.

The Frances Stern Food Clinic

At a recent meeting of the Administrative Committee of the Tufts College Medical School, Boston, a Committee on Nutrition was appointed to be designated The Frances Stern Committee on Nutrition in recognition of the teaching of applied dietetics for the past 16 years by Miss Stern and her associates at the Food Clinic of the Boston Dispensary as a part of the course in clinical medicine. The Food Clinic of the Dispensary is now called The Frances Stern Food Clinic by a vote of the Board of Managers at the Silver

Anniversary in 1943 as a tribute to its founder.

According to a recent announcement by the Medical School, the Charles Hood Dairy Foundation will contribute annually for three years half the estimated costs for a professor of nutrition at the Medical School, the work to be an integral part of both pre-clinical and clinical medicine and to include research. Prior to the appointment of such a person a study of nutrition in relation to medical teaching is under way.

BOOKS RECEIVED

- FUNDAMENTALS OF INTERNAL MEDICINE. By Wallace Mason Yater. 2nd ed. New York: D. Appleton-Century, 1944. 1204 pp. Price, \$10.00.

Wilfred N. Sisk, M.D., M.P.H., Director and Health Officer, Buncombe County Health Department, Asheville, N. C.

Hubert O. Swartout, M.D., Dr.P.H., Los Angeles County Health Officer, Los Angeles, Calif.

Julius R. Thebaud, D.D.S., Director General, National Public Health Service, Port-au-Prince, Haiti

Glen S. Usher, M.D., Chief, Bureau of Venereal Disease Control, State Health Department, Trenton, N. J.

Benjamin F. Wyman, M.D., State Health Officer, Columbia, S. C.

Laboratory Section

Luther A. Black, Ph.D., Senior Bacteriologist, U. S. Public Health Service, Cincinnati, O.

Donald C. A. Butts, D.Sc., Associate Professor of Bacteriology and Tropical Diseases, Georgetown University School of Medicine, Washington, D. C.

Geoffrey Edsall, M.D., Acting Director, Division of Biologic Laboratories, State Department of Public Health, Boston, Mass.

Carolyn R. Falk, B.A., Bacteriologist, Department of Health, New York, N. Y.

Stanley E. Hartsell, Ph.D., Associate Professor of Bacteriology, Purdue University, W. Lafayette, Ind.

Nell Hirschberg, Ph.D., Associate Bacteriologist, U. S. Public Health Service, Raleigh, N. C.

Melvin E. Koons, M.P.H., Director, Division of Laboratories, State Department of Health, Grand Forks, N. D.

Malcolm H. Merrill, M.D., Chief, Division of Laboratories, State Department of Public Health, Berkeley, Calif.

Pablo Morales Otero, M.D., Director and Professor of Bacteriology and Immunology, School of Tropical Medicine, San Juan, P. R.

Robert M. Perlman, M.D., M.S.P.H., Assistant Surgeon (R), National Cancer Institute, Bethesda, Md.

Leslie A. Sandholzer, Ph.D., Associate, U. S. Department of the Interior, College Park, Md.

Anna M. Sexton, Librarian, Division of Laboratories and Research, State Department of Health, Albany, N. Y.

Aimee Wilcox, Assistant Protozoologist, U. S. Public Health Service, Memphis, Tenn.

Vital Statistics Section

Anthony J. Borowski, Dr.P.H., Assistant in Biostatistics, Medical College of Virginia, and Statistician and Chief Clerk, Health Department, Richmond, Va.

Cornelius M. Bowen, Health Officer and Registrar of Vital Statistics, Boroughs of Westwood and Haworth, Westwood, N. J.

Clara E. Cuncell, M.S., Medical Research Officer, Office of Coordinator of Inter-American Affairs, Washington, D. C.

Paul M. Densen, D.Sc., Assistant Professor of Preventive Medicine and Public Health, Vanderbilt University Medical School, Nashville, Tenn.

Forrest E. Linder, Ph.D., Assistant Chief Statistician, Bureau of the Census, Washington, D. C.

Frances A. Macdonald, A.B. (formerly Director, Bureau of Vital Statistics, Board of Health, Hartford, Conn.)

Alan E. Treloar, Ph.D., Associate Professor of Biostatistics, School of Public Health, University of Minnesota, Minneapolis, Minn.

Engineering Section

Raymond F. Goudey, M.S.C.E., Sanitary Engineer, Department of Water and Power, Los Angeles, Calif.

John M. Henderson, C.E., Senior Sanitary Engineer (R), U. S. Public Health Service, Atlanta, Ga.

Glen J. Hopkins, B.S.C.E., Director, Division of Engineering, State Board of Health, Pierre, S. D.

Nelson H. Rector, B.E.C.E., Sanitary Engineer (R), U. S. Public Health Service, Atlanta, Ga.

Industrial Hygiene Section

Allan D. Brandt, Sc.D., Sanitary Engineer, U. S. Public Health Service, Chicago, Ill.

Irving Gray, M.D., Practitioner of Industrial Medicine; Member, Public Health Committee, and Chairman, Committee on Industrial Health, Kings County Medical Society; Member, Public Health Committee, Brooklyn Chamber of Commerce, Brooklyn, N. Y.

Food and Nutrition Section

Ernestine Becker, M.A., Associate in Biochemistry and Nutrition, Johns Hopkins School of Hygiene and Public Health, Baltimore, Md.

Anna E. Boller, Ph.B., Chief Dietitian, Central Free Dispensary, Rush Medical College, Chicago, Ill.

Lt. Col. Cecil G. Dunn, Q.M.C., Chief, Dehydration Section, Office of the Quartermaster General, U. S. Army, Washington, D. C.

Lloyd A. Hall, Sc.D., Chief Chemist, The Griffith Laboratories, Chicago, Ill.

Norman H. Jolliffe, M.D., Chief, Medical Service, Psychiatric Division, Bellevue Hospital, and Lecturer in Public Health Practice, College of Physicians and Surgeons, New York, N. Y.

Gordon W. Molyneux, Supervising Milk Inspector, Westchester County Department of Health, White Plains, N. Y.

Pearl Rorabaugh, M.S., Nutritionist, State Department of Health, Topeka, Kans.

Fredrick J. Stare, M.D., Ph.D., Associate Professor of Nutrition, Harvard School of Public Health, Boston, Mass.

Maternal and Child Health Section

Paul R. Ensign, M.D., M.P.H., Pediatric Consultant, State Department of Health, Atlanta, Ga.

Major Samuel B. Kirkwood, M.C., Ashford General Hospital, West Virginia (formerly Instructor in Obstetrics and Maternal Health, Harvard Medical School and School of Public Health)

Martha A. O'Malley, M.D., M.P.H., Assistant in Child Hygiene, Harvard School of Public Health, Boston, Mass.

Louis Spekter, M.D., M.P.H., Chief, Division of Crippled Children, State Department of Health, Hartford, Conn.

Blanca H. Trelles de Vazquez, M.D., Chief, Bureau of Crippled Children, Department of Health, Santurce, P. R.

L. C. Newton Wayland, M.D., Director, Maternal and Child Health, Santa Barbara County Health Department, Santa Barbara, Calif.

Public Health Education Section

Jean Christopher, M.S.P.H., Health Education Consultant, State Department of Public Health, Springfield, Ill.

Bertha A. Hess, M.S.P.H., Consultant on Mental and Social Hygiene, State Department of Health, Columbus, Ohio

Rae E. Kaufer, B.S.Ed., Assistant Health Education Consultant, U. S. Public Health Service, Bethesda, Md.

Philip L. Riley, M.A., Directing Supervisor, Bureau of Physical Welfare, Board of Education, Cleveland, Ohio

Lewis C. Robbins, M.D., M.P.H., Director, Wichita Health Unit, Wichita Falls, Tex.

Mabel E. Rugen, Ph.D., Associate Professor of Health Education, School of Public Health, University of Michigan, Ann Arbor, Mich.

Public Health Nursing Section

Bertha L. Allwardt, R.N., B.S., Associate Public Health Nursing Consultant, U. S. Public Health Service, Dallas, Tex.

Ada M. Beerstecher, R.N., M.A., Executive Secretary, Community Health and Civic Association, Ardmore, Pa.

Zella Bryant, R.N., Assistant Chief Nurse, Nursing Section, Medical Division, Office of Civilian Defense, U. S. Public Health Service, 610 South Canal, Room 852, Chicago, Ill.

Elizabeth Curtis, R.N., M.A., Assistant Public Health Nursing Consultant, U. S. Public Health Service, New Orleans, La.

Josephine L. Daniel, R.N., B.S., Director, Division of Public Health Nursing, State Health Department, Oklahoma City, Okla.

Winifred Devlin, R.N., M.S., Instructor in Public Health Nursing and Field Coordinator, School of Nursing, Catholic University, Washington, D. C.

G. Aileen Dyer, R.N., B.S., Director, Division of Public Health Nursing, State Board of Health, Portland, Ore.

Marion Ferguson, R.N., Ph.D., Public Health Nursing Consultant, U. S. Public Health Service, Chicago, Ill.

Theodora A. Floyd, R.N., M.A., Regional Consultant Nurse, U. S. Children's Bureau, Atlanta, Ga.

Ruth B. Freeman, R.N., A.M., Associate Professor and Director, Course in Public Health Nursing, School of Public Health, University of Minnesota, Minneapolis, Minn.

Lillian A. Gardiner, R.N., M.S., Director, Division of Public Health Nursing, Territorial Department of Health, Juneau, Alaska

Ruth G. George, R.N., State Supervising Nurse, State Board of Health, Columbia, S. C.

Edna S. Gould, R.N., B.S., Field Coordinator and Instructor of Public Health Nursing, Indiana University, Bloomington, Ind.

Lily C. Hagerman, R.N., B.S., Public Health Nursing Consultant, U. S. Public Health Service, Kansas City, Mo.

Hazel G. Herringshaw, R.N., M.Ed., Assistant Professor of Public Health Nursing, University of Michigan, Ann Arbor, Mich.

E. Doris Johnson, R.N., M.S., Public Health Nursing Consultant, U. S. Public Health Service, New York, N. Y.

A. Louise Kinney, R.N., M.A., Director, Division of Public Health Nursing, St. Louis University School of Nursing, St. Louis, Mo.

Florence Manley, R.N., M.A., District Supervising Nurse, State Department of Health, Buffalo, N. Y.

Lucy E. Massey, R.N., M.A., Nurse Member, School Health Coordinating Unit, State Board of Health, Jackson, Miss.

Anne H. McCabe, R.N., M.A., Director, Division of Public Health Nursing, Westchester County Health Department, White Plains, N. Y.

Leon G. Schwartz, 283 Austin St., West Newton, Mass., Student, Middlesex University School of Veterinary Medicine

William M. Shanahan, M.D., 2740 Oahu Ave., Honolulu 15, Hawaii, Acting Director, Bureau of Mental Hygiene, Board of Health

DECEASED MEMBERS

Julia George, Berkeley, Calif., Elected Member 1920, Public Health Nursing Section

Wilhelm O. Johnson, Springfield, Mass., Elected Member 1939, Public Health Education Section

SELSKAR MICHAEL GUNN

Selskar Michael Gunn, Vice-President of the Rockefeller Foundation, and Executive Secretary of the A.P.H.A. and Editor of the JOURNAL from 1912 to 1918, died on August 2 at the age of 61.

Mr. Gunn was born in London, England, where he attended Kensington Park College. In 1900, he came to the United States and was graduated from Massachusetts Institute of Technology with a B.S. degree in 1905. He received a C.P.H. degree from the Harvard-M.I.T. School of Public Health in 1917. From 1905 to 1914, he served the Boston Biochemical Laboratory as bacteriologist; the Iowa State Board of Health in the same capacity; Orange,

N. J., as Health Officer; and Massachusetts Institute of Technology as an instructor and later a professor in sanitary biology and public health. From 1914 to 1916, he was the Director of the Division of Hygiene of the Massachusetts Department of Health. Mr. Gunn was Associate Director of the Commission for the Prevention of Tuberculosis in France, functioning under the auspices of the Rockefeller Foundation and French health authorities from 1917 to 1920. For two years thereafter he was adviser to the Ministry of Health of Czechoslovakia, and in 1922 returned to France to become Director of the Paris Office of the International Health Board of the

Rockefeller Foundation, directing health work throughout Europe. He became Vice-President of the Rockefeller Foundation in 1927 and remained in Paris until 1932. From 1932 to 1937 he headed a Foundation program in China designed to reconstruct that nation's agricultural, educational, and health methods. He then returned to this country and engaged in Foundation work in New York. In 1941, the Foundation lent his services to the National Health Council to direct a three year study of voluntary health agencies in the United States. From January, 1943, to March, 1944, he had been lent by the Council to assist former Governor Herbert H. Lehman of New York, Director General of UNRRA. He served the Association as Vice-President in 1941, and at the time of his death was a member of the Governing Council.

A.P.H.A. MERIT SYSTEM UNIT REPORTS PROGRESS

Reginald M. Atwater, M.D., Director of the A.P.H.A. Merit System Unit established to prepare examination material for professional public health workers, announces that the Unit has completed 97 examinations in the field of public health for 18 states and 1 city. Examination material is now available for public health nurses, for administrative health officers, for laboratory workers, and for workers in environmental sanitation, both engineers and sanitarians. Test items are also available in the fields of nurse-midwifery and othopedic nursing.

Lillian Dick Long, Ph.D., is psychometrician for the Unit which is cooperating with state merit systems and civil service agencies and with the U. S. Public Health Service and the U. S. Children's Bureau.

**Preliminary Program of the Scientific Sessions of
the Second Wartime Public Health Conference
and the 73rd Annual Business Meeting of the
American Public Health Association, and Meetings
of Related Organizations**

New York, N. Y.

October 2, 3, 4, and 5, 1944

THE Annual Meeting Program Committee offers a preview of the content of scientific sessions planned in connection with the Second Wartime Public Health Conference and the 73rd Annual Business Meeting in New York, N. Y. In many instances, sessions are complete. In others, places are purposely left open for important matters which may develop before October. Inaccuracies and omissions are to be expected, and it is hoped they will be excused. The professional affiliations and addresses of speakers are not given, but a complete index to participants will be published in the final program, which will be distributed to all delegates at the Registration Desk, Hotel Pennsylvania. Registration headquarters will be opened at 9:30 A.M. on Monday, October 2.

MONDAY MEETINGS

The Classroom Teacher Relates the Health Program to Wartime
Needs. MARIE SWANSON.

Administrator's Viewpoint on the School Health Program. EUGENE
B. ELLIOTT.

Presentation of William A. Howe Award.

AMERICAN SOCIAL HYGIENE ASSOCIATION

8:30 P.M. *Salle Moderne, Hotel Pennsylvania—Open Meeting.*

INDUSTRY VS. V.D.—A PROGRAM OF EDUCATION AND ACTION

Presiding: VICTOR G. HEISER, M.D.

Speakers:

R. E. GILLMOR

W. L. WEAVER, M.D.

ABRAHAM BLUESTEIN

PERCY SHOSTAC

MONDAY MEETINGS (Cont.)

SYMPOSIUM ON CANCER

9:30 A.M. *Georgian Room, Hotel Pennsylvania.*

Presiding: HERBERT L. LOMBARD, M.D.

Recent Progress in the Successful Treatment of Advanced Cancer.
WILLIAM E. HOWES, M.D.

Discussion: IRA I. KAPLAN, M.D.

Possibilities in Cancer Case Finding. MORTON L. LEVIN, M.D.

Cancer Prevention Clinics. ELISE S. L'ESPERANCE, M.D.

Discussion: CATHERINE MACFARLANE, M.D.

Recent Advances in Cancer Research. WILLIAM H. WOGLOM, M.D.

Discussion: E. V. COWDRY, M.D.

2:30 P.M. *Georgian Room, Hotel Pennsylvania.*

Malignant Tumors in Relation to War Personnel. MAJOR MILTON J. FRIEDMAN, M.C.

Cancer Morbidity in the United States. SELWYN D. COLLINS, PH.D.

The Statistical Approach to Cancer Control in Massachusetts.
EVELYN A. POTTER and MILDRED R. TULLY.

Discussion: ELEANOR J. MACDONALD.

The Need for Cancer Education in Secondary Schools. F. L. RECTOR, M.D.

Discussion: EDMUND G. ZIMMERER, M.D.

8:00 P.M. *Georgian Room, Hotel Pennsylvania.*

Presiding: LOUIS I. DUBLIN, PH.D.

The Rôle of Nonofficial Agencies in Cancer Control. J. LOUIS NEFF.

The Rôle of the Federal Government in Cancer Control. R. R. SPENCER, M.D.

The Rôle of State Health Departments in Cancer Control. LOUIS C. KRESS, M.D.

CONFERENCE OF INDUSTRIAL NURSING
CONSULTANTS

10:00 A.M. *North Ball Room, Hotel New Yorker.*

2:00 P.M. *North Ball Room, Hotel New Yorker.*

MONDAY MEETINGS (Cont.)

CONFERENCE OF MUNICIPAL PUBLIC HEALTH
ENGINEERS

10:00 A.M. 18th floor headquarters, Hotel Pennsylvania.

2:30 P.M. 18th floor headquarters, Hotel Pennsylvania.

CONFERENCE ON RECIPROCAL SANITARY
MILK CONTROL

4:30 P.M. Roof Garden North, Hotel Pennsylvania.

CONFERENCE OF STATE AND PROVINCIAL PUBLIC
HEALTH LABORATORY DIRECTORS

9:30 A.M. Conference Room 2, Hotel Pennsylvania.

SHEAHAN, R.N.

National Unity in Public Health Nursing. ALMA C. HAUPT, R.N.

NATIONAL PUBLICITY COUNCIL FOR HEALTH
AND WELFARE SERVICES

9:30 A.M. Hotel New Yorker.

A CLINIC ON PRINTED MATTER

A practical analysis of printed pieces in the health field. Emphasis on
selection of the kind of lay-out and copy which will best accomplish the
particular job each piece is intended to do.

MONDAY MEETINGS (Cont.)

NATIONAL PUBLICITY COUNCIL FOR HEALTH
AND WELFARE SERVICES (Cont.)

2:30 P.M. *Hotel New Yorker.*

A CLINIC ON RADIO

A clinical discussion of the various types of radio programs (dramatizations, interviews, talks, etc.) with emphasis on the advantages and limitations of each for carrying different kinds of health messages.

SESSIONS FROM TUESDAY, OCTOBER 3, TO THURSDAY,
OCTOBER 5, INCLUSIVE

Hotel Pennsylvania

TUESDAY, 9:30 A.M.

LABORATORY

First Session—Salle Moderne

Presiding: C. A. PERRY, Sc.D., *Chairman.*

Section Business.

Report of the Coördinating Committee on Standard Methods. *Chairman,* LIEUTENANT COLONEL A. PARKER HITCHENS, M.C.

Report of the Standard Methods Committee on Virus and Rickettsial Diseases. *Chairman,* THOMAS FRANCIS, JR., M.D.

Report of the Standard Methods Committee on Examination of Water and Sewage. *Chairman,* WALTER L. MALLMANN, Ph.D.

Report of the Standard Methods Committee on Examination of Milk and Milk Products. *Chairman,* ROBERT S. BREED, Ph.D.

Report of the Standard Methods Committee on Biology of the Laboratory Animal. *Acting Chairman,* PAUL A. MOODY, Ph.D.

Report of the Standard Methods Committee for Frozen Desserts and Ingredients. *Chairman,* FRIEND LEE MICKLE, Sc.D.

Report of the Standard Methods Committee on Biological Products. *Acting Chairman,* HAROLD W. LYALL, Ph.D.

Report of the Standard Methods Committee for the Examination of Shellfish. *Chairman,* JAMES GIBBARD.

Report of the Standard Methods Committee for the Examination of Germicides and Antibacterial Agents. *Chairman,* STUART MUDD, M.D.

TUESDAY, 9:30 A.M.

LABORATORY (Cont.)

Report of the Laboratory Section Representative on the Commission for the Study of Biological Stains. WILLIAM D. STOVALL, M.D.

Report of the Section Archivist. ANNA M. SEXTON.

FORUM DISCUSSION

DIAGNOSTIC PROCEDURES AND REAGENTS

Leader: WILLIAM D. STOVALL, M.D.

An open discussion of the Methods and Reagents presented in the forthcoming new (2nd) edition of the book published by the Standard Methods Committee on this subject with special emphasis on the chapters appearing in this edition for the first time.

HEALTH OFFICERS

First Session—Georgian Room

Presiding: JOSEPH H. KINNAMAN, M.D., *Chairman*

Section Business.

LOCAL HEALTH ADMINISTRATION

Panel Leader: C.-E. A. WINSLOW, DR.P.H.

Participants:

CARL E. BUCK, DR.P.H.
L. E. BURNEY, M.D.
HAVEN EMERSON, M.D.
T. PAUL HANEY, M.D.
J. ROY HEGE, M.D.
R. P. KANDLE, M.D.
G. F. MOENCH, M.D.
E. V. THIEROFF, M.D.

ENGINEERING SECTION, CONFERENCE OF STATE
SANITARY ENGINEERS, AND CONFERENCE OF
MUNICIPAL PUBLIC HEALTH ENGINEERS

Joint Session—Madhattan Room

Presiding: SOL PINCUS, C.E., F. HOLMAN WARING, and J. LLOYD BARRON, C.E.

First Session—Parlor C

Presiding: LEONA BAUMGARTNER, M.D., *Chairman.**Section Business.*

TUESDAY, 9:30 A.M.

FOOD AND NUTRITION

First Session—Roof Garden North

Presiding: DONALD K. TRESSLER, PH.D., *Chairman.*

NUTRITIONAL AND SANITARY ASPECTS OF FOOD EATEN
OUTSIDE THE HOME

Retention of Vitamin Values in Large Scale Food Service. FAITH FENTON, PH.D.

Nutritional Problems that Arise in Large Scale Feeding Operations. LIEUTENANT COMMANDER C. M. MCCAY, H-V (S), USNR.

Making Food Handlers Health Conscious. H. A. MORGAN, JR., M.D., MRS ALBERTINE P. MCKELLAR, and TOM B MUSE.

Section Business:

Report of the Secretary. MARJORIE M. HESELTINE.

Report of the Coördinating Committee. *Chairman*, F. C. BLANCK, PH.D.

Report of the Committee on Microbiological Examination of Foods. *Chairman*, HARRY E. GORESLINE, PH.D.

Report of the Committee on Milk and Dairy Products. *Chairman*, J. A. KEENAN, PH D.

Report of the Committee on Foods (except milk). *Chairman*, BERNARD E. PROCTOR, PH D.

Report of the Joint Committee on Analyzing Frozen Desserts. *Chairman*, FREDERICK W. FABIAN, PH.D.

Report of the Committee on Nutritional Problems. *Chairman*, C. G. KING, PH D.

Report of the Committee on Membership and Fellowship. *Chairman*, RACHAEL L. REED.

Election of Officers.

Note: There will be a meeting of the Section Council immediately following this session.

VITAL STATISTICS

First Session—Parlor 2

Presiding: SELWYN D. COLLINS, PH.D., *Chairman.*

WAR AND THE BIRTH RATE

Historical paper on "War and the Birth Rate." LOUIS I. DUBLIN, PH.D.

Discussion: RICHARD N. WHITFIELD, M.D.

Recent Changes in the Birth Rate. A. W. HEDRICH, Sc.D.

TUESDAY, 9:30 A.M.

VITAL STATISTICS (Cont.)

Discussion: J. V. DePORTE, PH.D.

Effect of the Increased Birth Rate on Public Health Programs. JOHN M. SAUNDERS, M.D.

Discussion: HAVEN EMERSON, M.D.

Effect of Increased Birth Rate on Future Population. P. K. WHELPTON.

Discussion: A. J. LOTKA, D.Sc.

Committee Reports.

Section Business

TUESDAY, 2:30 P.M.

VITAL STATISTICS AND FOOD AND NUTRITION
SECTIONS

Joint Session—Georgian Room

Presiding: SELWYN D. COLLINS, PH.D., and DONALD K. TRESSLER, PH.D.

STATISTICAL RESEARCH IN HUMAN NUTRITION

Statistics as an Essential Feature in Human Nutrition. E. J. BIGWOOD, M.D.

Clinical Tests of the Nutritional State. DOROTHY G. WIEHL and H. D. KRUSE, M.D.

Methods of Dietary Investigation. RUTH LOIS HUENEMANN.

Microanalytical Methods in Nutritional Surveys of Children. OTTO A. BESSEY, PH.D.

Statistical Methods in Using Anthropometric Data in the Field of Nutritional Research. RACHEL M. JENSS, Sc.D.

Results of a Survey with Emphasis on Interpretation. WILLIAM D. ROBINSON, M.D.

INDUSTRIAL HYGIENE

Second Session—Roof Garden South

The Federal-State Rehabilitation Program. DEAN CLARK, M.D.

Industrial Diseases in the Beryllium Industry. Speaker to be announced.

Is Dermatophytosis a Significant Occupational Health Problem? Speaker to be announced.

Report of the Committee on Anthrax. *Chairman,* HENRY FIELD SMYTH, M.D.

TUESDAY, 2:30 P.M.

EPIDEMIOLOGY, HEALTH OFFICERS, LABORATORY,
ENGINEERING AND SCHOOL HEALTH SECTIONS

Joint Session—Ball Room

Presiding: LIEUTENANT COLONEL GAYLORD W. ANDERSON, M.C.

THE CONTROL OF AIR-BORNE INFECTIONS

Epidemiologic Observations on the Application of Triethylene Glycol Vapor for Air Sterilization. EDWARD BIGG, M.D., BURGESS H. JENNINGS, and FRANKLYN C. W. OLSON.

Principles of Ultra-violet Disinfection of Enclosed Spaces. L. J. BUTOLPH, Sc.D.

Ultra-violet Light Control of Air-borne Infections in Naval Training Stations. LIEUTENANT (s.g.) STAFFORD M. WHEELER, M.C., USNR, LIEUTENANT (s.g.) HOLLIS S. INGRAHAM, USNR, M.C., ALEXANDER HOLLAENDER, PH.D., LIEUTENANT COMMANDER NICHOLAS D. LILL, M.C., USNR, and LIEUTENANT COMMANDER JACOB GERSHON-COHEN, M.C., USNR.

Irradiation of Classroom Atmospheres. THEODORE S. WILDER, M.D.

Prophylaxis of Respiratory Diseases in the Navy Through Mass Administration of Sulfadiazine. COMMANDER ALVIN F. COBURN, M.C., USNR.

Prophylaxis of Respiratory Diseases in the Army Air Force Through Mass Administration of Sulfonamide Drugs. CAPTAIN RICHARD HODGES.

DENTAL HEALTH

First Session—Parlor 2

Presiding: KENNETH A. EASLICK, D.D.S., *Chairman.**Section Business.*

A NATIONAL DENTAL CARE PROGRAM

Presentation of the Dental Problem. JOHN T. FULTON, D.D.S.

Services to be Rendered. VERN D. IRWIN, D.D.S.

Requirements for Safeguarding Interests of the Profession and the Public. CAPTAIN C. RAYMOND WELLS.

The Manpower Problem. BION R. EAST, D.D.S.

Administration of a National Dental Care Program. RICHARD C. LEONARD, D.D.S.

Methods of Financing. GEORGE A. NEVITT, D.D.S.

The Contribution of Dental Hygienists. MARGARET H. JEFFREYS.

The Contribution of Health Educators. ANNIE TAYLOR.

TUESDAY, 2:30 P.M.

MATERNAL AND CHILD HEALTH

First Session—Roof Garden North

Presiding: MYRON E. WEGMAN, M.D., *Chairman.*

MEDICAL SERVICES FOR MIGRANTS WITH SPECIAL EMPHASIS UPON CARE FOR MOTHERS AND CHILDREN

From the Point of View of Community War Services. HARRIET RINALDO.

Care of Mothers and Infants in Migratory Labor Camps. KATHERINE BAKER, R.N.

Health Services for School Children on Farms. Speaker to be announced.

Health Services in Migratory Labor Camps (War Food Administration Program). FREDERIC D. MOTT, M.D.

Section Business.

PUBLIC HEALTH EDUCATION

First Session—Madhattan Room

Presiding: CARL A. WILZBACH, M.D.

WHAT THE HEALTH OFFICER EXPECTS FROM THE HEALTH EDUCATOR AND VICE VERSA

Panel Leader: H. O. SWARTOUT, M.D.

Participants:

W. W. PETER, M.D.

W. W. BAUER, M.D.

LOUISA J. ESKRIDGE

HELEN MARTIKAINEN

D. A. DUKELOW, M.D.

Recognition of New Members and Fellows.

Report of Committee on Health Education in Hospitals, Out-Patient Departments and Clinics. *Chairman,* W. W. BAUER, M.D.

Section Business.

PUBLIC HEALTH NURSING

First Session—Salle Moderne

Presiding: MARION H. DOUGLAS, R.N., *Chairman.*

Section Business.

Psychosomatic Problems in Today's Health Program

(a) Public Health Aspects.

(b) Contribution of the Public Health Nurse to Prevention and Care.

(c) Preparation of the Public Health Nurse.

Speakers to be announced.

TUESDAY, 5:00 P.M.

NATIONAL COMMITTEE OF HEALTH COUNCIL
EXECUTIVES

Conference Room 2

TUESDAY, 8:30 P.M.

FIRST GENERAL SESSION

Ball Room

Presiding: FELIX J. UNDERWOOD, M.D., *President*, American Public Health Association.

Addresses of Welcome:

THE HONORABLE FIORELLO H. LAGUARDIA

ERNEST L. STEBBINS, M.D., *Commissioner of Health*

EDWARD S. GODFREY, JR., M.D., *State Commissioner of Health*

LEVERETT D. BRISTOL, M.D.

Public Health as an International Problem. Third Annual Delta Omega Lecture. RAYMOND B. FOSDICK, LL.D.

Local Responsibility in Public Health Administration. JOHN J. SIPPY, M.D., *President-elect*, American Public Health Association.

Presentation of the Sedgwick Memorial Medal Award.

Reception to the President and the President-elect.

WEDNESDAY, 9:30 A.M.

EPIDEMIOLOGY

Second Session—Roof Garden South

Epidemiological Studies on Infectious Hepatitis. MAJOR W. P. HAVENS, JR., M.C., ROBERT WARD, M.D., and V. A. DRILL, PH.D.

Control Measures Against Importation of Disease by Men Returning from Overseas Duty. LIEUTENANT COLONEL JOHN W. R. NORTON, M.C.

Venereal Disease Epidemiology in Wartime. JOHN R. HELLER, JR., M.D.

Comparison of Mortality in Selective Service Registrants with Negative and Positive Serologic Tests for Syphilis. MURRAY C. BROWN, M.D.

The Distribution of Poliomyelitis Virus During an Epidemic in an Urban Area. HAROLD E. PEARSON, M.D., GORDON C. BROWN, SC.D., ROBERT C. RENDTORFF, SC.D., GERALD M. RIDENOUR, PH.D., and THOMAS FRANCIS, JR., M.D.

Field Study of the Prevalence of Clinical Manifestations of Dietary Inadequacy. WILLIAM J. DARBY, M.D., and D. F. MILAM, M.D.

WEDNESDAY, 9:30 A.M.

FIRST SPECIAL SESSION

Ball Room

Presiding: THOMAS PARRAN, M.D.

TODAY'S GLOBAL FRONTIERS IN PUBLIC HEALTH

For South America. MAJOR GENERAL GEORGE C. DUNHAM.

For China. SZEMING SZE, M.D.

HEALTH OFFICERS AND FOOD AND NUTRITION
SECTIONS

Joint Session—Georgian Room

Presiding: JOSEPH H. KINNAMAN, M.D., and DONALD K. TRESSLER, PH.D.

PUBLIC HEALTH NUTRITION SERVICES IN WARTIME

Panel Leader: CARL H. NEUPERT, M.D.

Participants:

VIVIAN DRENCKHAHN

L. L. FATHERREE, M.D.

FLORENCE B. HOPKINS, M.D.

M. H. KRONENBERG, M.D.

E. W. MCHENRY, PH.D.

I. H. MOORE, M.D.

MARIE NEUSCHAEFER, R.N.

MARY STANSEL

ENGINEERING

First Session—Parlor 2

Presiding: SOL PINCUS, C.E., *Chairman.*

TOOLS FROM THE WAR—AVAILABLE

A Demonstration in Food and Utensil Sanitation. MURRAY P. HORWOOD, PH.D.

Disinfection of Small Water Supplies. GORDON M. FAIR.

Bacteriological Improvements Obtained by the Practice of Break-point Chlorination. A. E. GRIFFIN and N. S. CHAMBERLIN.

Factors in Water Quality Control in the U. S. Army. COLONEL W. A. HARDENBERGH, SN.C.

Section Business.

WEDNESDAY, 9:30 A.M.

MATERNAL AND CHILD HEALTH AND PUBLIC
HEALTH NURSING SECTIONS

Joint Session—Madhattan Room

Presiding: MYRON E. WEGMAN, M.D., and MARION H. DOUGLAS, R.N.

STREAMLINING HOSPITAL TECHNICIS

From the Point of View of a Supervising Nurse on a Maternity
Service. BERTHA PIERACCINI, R.N.From the Point of View of a Public Health Nurse Examining Mater-
nity Hospital Services for License. RUTH OLSIN, R.N.From the Point of View of the Public Health Physician. VIKTOR O.
WILSSON, M.D.

From the Point of View of the Epidemiologist. JAMES WATT, M.D.

LABORATORY

Second Session—Roof Garden North

Section Business.

A SERIES OF ABRIDGED PAPERS

Excretion of Typhoid Bacilli by Carriers—Comparative Value of Fecal
and Bile Specimens in Their Detection. HOWARD J. SHAUGHNESSY,
Ph.D., and FRANCES FRIEVER.The Laboratory Criteria of the Cure of Typhoid Carriers. ROY F.
FEEMSTER, M.D.Preparation of a Potent "Washed" Typhoid Vaccine. MORRIS F.
SHAFFER, Ph.D., LESLIE WETTERLOW and GEOFFREY EDSALL, M.D.

Meningococcus Typing. SARA E. BRANHAM, M.D.

Comparative Results Obtained with the Kahn Standard and a One-
Tube Flocculation Procedure in Serologic Tests for Syphilis.
SAMUEL R. DAMON, Ph.D., and MAYME C. COLVIN.Laboratory Diagnosis by Complement-Fixation. LIEUTENANT LOUIS H.
MUSCHEL, Sn.C.The Effect of Environmental Temperature on Experimental Influenza
in Mice. S. EDWARD SULKIN, Ph.D.An Outbreak of Food Poisoning Due to a New Etiological Agent—
Salmonella Berta. GEORGE H. HAUSER, M.D., and W. L. TREUTING,
M.D.The Development in vitro of Penicillin-fast Strains of the Gonococcus.
CHARLES M. CARPENTER, M.D.

Transportation of Gonococcus Specimens. NELL HIRSCHBERG, Ph.D.

The Preparation of Crude Penicillin and Its Laboratory Use. LILLIAN
BUXBAUM.

WEDNESDAY, 9:30 A.M.

LABORATORY (Cont.)

A New Method for the Determination of the Self-Sterilizing Ability of Parenteral Preparations. DWIGHT A. JOSLYN.

Non-Acid-Fast Forms of the Tubercle Bacillus as Shown by Improved Staining Technic. ELEANOR ALEXANDER-JACKSON, PH.D.

PUBLIC HEALTH EDUCATION AND SCHOOL HEALTH
SECTIONS, AND THE AMERICAN SCHOOL
HEALTH ASSOCIATION

Joint Session—Sal'e Moderne

Presiding: CHARLES C. WILSON, M.D.

CONTRIBUTION OF PUBLIC HEALTH WORKERS TO THE
PREPARATION OF TEACHERS

New Developments in Teacher Education (with implications for health preparation). MAURICE TROYER, PH.D.

New Developments in Education of Public Health Personnel for School Health Work.

- (a) Summary of Report of Committee on Qualifications of School Physicians. GEORGE M. WHEATLEY, M.D.

Woman or draft exempt man, to take charge of newly established, newly equipped laboratory. Must be able to carry out all the usual procedures of a public health laboratory. Write full details including minimum starting salary requirement. All letters including vitae and photo will be promptly acknowledged. Address E. E. Palmquist, M.D., King County Health Department, 402-L County-City Building, Seattle 4, Wash.

Wanted: A Vital Statistician to assume directorship of the Bureau of Vital Statistics in a large northeastern city.

Salary \$2,500-\$3,100, plus cost of living adjustment. Write Box G, Employment Service, A.P.H.A.

Wanted: County Public Health Nurse for midwestern state. Present salary \$160 per month and travel allowance. Must have had previous experience in public health. Own and drive car. Address District Health Unit 2, West Branch, Mich.

Physician—public health pediatrics. To assist director of maternal and child health in a large California County Health Department. Major duties, conducting of infant and preschool health conferences and school examinations. Beginning salary \$390 a month and travel allowance. California license required. Training and experience in pediatrics or public health or both. Immediately available. Address William C. Buss, M.D., Kern County Health Dept., Bakersfield, Calif.

Wanted: Physician with tuberculosis training to direct Tuberculosis Division of Milwaukee Health Dept. Salary \$4,200 per year plus cost of living wage adjustment. If interested contact Dr. G. F. Burgardt, Milwaukee Health Dept., Milwaukee, Wis.

Southern Wisconsin county announces position now open for supervising public health nurse. Office is located in city containing state capitol and university. Staff consists of two nurses. Requirements are degree of bachelor of science in public health nursing, 2 or 3 years' experience as staff nurse, some experience as supervising nurse. Must be eligible for certification as public health nurse in Wisconsin. Beginning salary \$185. Write Box Z, Employment Service, A.P.H.A.

Wanted: Physician in eastern city of 190,000 population as Director of Bureau of Maternal & Child Hygiene. Salary \$4,500-\$5,031 plus cost of living adjustment. Box U, Employment Service, A.P.H.A.

Wanted: Two full-time public health nurses. Salary to start \$165 plus \$15 War Bonus per month. Car mileage paid at rate of 5¢ per mile. Write Box Q, Employment Service, A.P.H.A.

Wanted: Superintendent and Medical Director for tuberculosis sanatorium having 65 bed capacity and average of 35 patients per day. Salary \$4,380 with \$300 annual allowance for car. Write M. P. Hunter, City Manager, Roanoke, Va.

Wanted: Industrial hygienist to conduct surveys of industrial plants for large insurance company with complete laboratory facilities and field testing equipment. This is an excellent opportunity for a permanent, not a war period, position. State age, family status, education, experience, qualifications, and minimum salary. Write Box O, Employment Service, A.P.H.A.

Public Health Nurse, supervisory work in orthopedics, must have certificate in public health. Salary \$2,050 with maintenance of car, meals and upkeep while in the field. Address Dr. R. G. Beachley, Director of Health & Welfare, Arlington Co. Health Dept., 1800 N. Edison St., Arlington, Va.

Wanted: Staff nurses for 200 bed municipal tuberculosis hospital. Salary \$190 per month, \$35 per month deduction if maintenance desired. Educational program with opportunity for post-graduate work with University credit planned. For full information write Superintendent of Nurses, Firland Sanatorium, Richmond Highlands, Wash.

Wanted: Health officer for County-City health unit. Good opportunity for right man. Salary to start \$4,500 per year and travel expenses. Position permanent. Address G. F. Campana, M.D., Acting State Health Officer, Bismarck, N. D.

Wanted: Bacteriologist to direct and operate a modern public health laboratory in southeastern city of 70,000 population. Examinations 1,500 to 2,000 a month, largely serological and milk tests. Salary available to start \$2,400 per annum increasing to \$2,700 for satisfactory service. Assistant bacteriologist also needed, with available salary of \$1,800 increasing to \$2,000 if satisfactory service is shown. Write Box N, Employment Service, A.P.H.A.

Wanted: School dentist to direct and operate school dental program in southeastern city of 70,000 population. Salary available starting at \$3,600 and increasing to \$4,000 for satisfactory service. For further particulars write Box Y, Employment Service, A.P.H.A.

Wanted: An assistant in Health Division Council of Social Agencies, interested in community organization and health education. Large city and metropolitan area. State age, training and experience. Write Box X, Employment Service, A.P.H.A.

Wanted: Health Educator, preferably unmarried man with experience in venereal disease control. Work chiefly in suburban areas. Some evening work. Good salary with very generous travel allowance. Position under Civil Service with annual increases in salary. Address Venereal Disease Division, Wayne County Health Dept., 5716 Schaefer Rd., Dearborn, Mich.

Wanted: Public health nurse for staff work on a generalized program. Private agency, 45 hour week. Location 30 miles

from New York City. Salary first year, \$1,859.54; second year, \$2,009.54; maximum salary \$2,217.60. Transportation supplied, 24 working days' vacation annually. Write Box V, Employment Service, A.P.H.A.

Wanted: Director of Maternal and Child Health for Santa Barbara County Health Department. Salary \$4,500 per year, all expenses furnished. Write Dr. L. C. Newton Wayland, Santa Barbara Co. Health Dept., Santa Barbara, Calif.

FOR OTHER POSITIONS AVAILABLE WRITE EMPLOYMENT SERVICE, AMERICAN PUBLIC HEALTH ASSOCIATION, 1790 BROADWAY, NEW YORK 19, N. Y.

In view of the current active demand for trained and experienced persons in public health, it is suggested that prospective employers communicate directly with the Employment Service, American Public Health Association, 1790 Broadway, New York 19, N. Y., for up-to-date lists of applicants.

POSITIONS WANTED

ENGINEER

Well qualified public health engineer seeks responsible position in New York metropolitan area. E-480

Sanitary Engineer, C.E. 22 years' experience as sanitary engineer, 14 as director in state health department, now employed. Desires change. Location immaterial. E-481

LABORATORY

Research bacteriologist - veterinarian, now in civil service, desires change to direct or indirect war work. P-3 classification. Considerable laboratory and field experience. Used to foreign travel; will go anywhere. Steady hard worker. L-470

Bacteriologist, -29, draft exempt, 3 years' experience public health laboratory, 2 years' experience industrial organization. Experienced in investigation and control activities on water, sewage, and sanitation as chemist, bacteriologist and serologist in syphilis and enteric diseases. L-465

Bacteriologist-Serologist, male, with 20 years' experience in state and municipal public health laboratories, last 10 years in administrative capacity, now in charge of a midwest diagnostic laboratory, wishes to make a permanent change. L-427

HEALTH EDUCATION

Woman with background of nursing administration and health education seeks position in health education field. H-509

STATISTICS

Woman with background of statistics and epidemiology involving administration seeks position in statistical administration. Salary \$3,500 or over. S-460

MISCELLANEOUS

Sanitarian-Veterinarian, age 23, seeks employment in public health field. Experienced as veterinarian, serologist, sanitary inspection. M-460

NEWS FROM THE FIELD

U. S. ARMY DEVELOPS CIVIL PUBLIC HEALTH DIVISION

It has been announced that the Office of The Surgeon General, U. S. Army, Washington, has added a Civil Public Health Division under the Preventive Medicine Service. Warren F. Draper, M.D., Deputy Surgeon General, U. S. Public Health Service, has been appointed Chief of the Public Health branch of the Civil Affairs Section at the supreme headquarters of the Allied Expeditionary Force and will serve the Army with the rank of Brigadier General.

According to the announcement, the purpose of the new division is to develop plans pertaining to public health policy and practice in occupied and liberated territories. The division is directed by Colonel Thomas B. Turner who has recently made a tour of European and Mediterranean theaters of operation. Colonel Turner formerly was Director of the Venereal Disease Control Division, and is on leave as Professor of Bacteriology at the Johns Hopkins University School of Hygiene and Public Health.

The Allied Armies, according to the announcement, will be called upon to assume a measure of responsibility for civilian public health in many areas, entailing supervision of or liaison with local public health officials and the provision of certain necessary medical supplies. To accomplish its objective the Army plans to commission from civil life a number of officers experienced in public health administration and in specialties such as epidemiology, nutrition, and maternal and child hygiene. Candidates should be under 50 years of age and be qualified physically to perform at least limited

service duties overseas. Men selected will undergo a course of training at the School of Military Government, Charlottesville, Va., and at the Civil Affairs Training School, Yale University.

Instruction will include the theory and general principles of military government and liaison and the language and background of certain Far Eastern areas. Provision will also be made for training men in special phases of public health and certain medical specialties. Further information may be obtained by addressing the Surgeon General of the U. S. Army, Washington 25, D. C., attention Civil Public Health Division.

ONTARIO CANCER CONTROL FOUNDATION

According to the *Journal of the American Medical Association*, a Cancer Control Foundation for Ontario has been established through a legislative appropriation of \$500,000. The Foundation has been empowered to acquire lands and buildings and to employ a director, officers, and the necessary clerical staff. Lt. Col. A. L. Bishop, Toronto, is Chairman of the Foundation.

FEDERAL SERVICES REQUIRE SANITARY ENGINEERS

On July 15, 1944, a procurement objective for 211 sanitary engineers for the Sanitary Corps, U. S. Army, was announced by the Chief, Procurement Division, Army Service Forces, Washington, D. C. At the same time the U. S. Public Health Service made known a need for 100 additional sanitary engineers.

Sanitary engineers are urged to get in touch with their State Advisers, Pro-

curement and Assignment Service, in each state, for additional information concerning the needs and opportunities for service. These State Advisers will determine those sanitary engineers essential for protection of civilian public health, and will issue certificates of availability to those who can be released for service.

The U. S. Public Health Service has recently assigned a Commissioned Officer, E. S. Tisdale, Sanitary Engineer, to head the Procurement and Assignment Service for Sanitary Engineers, War Manpower Commission, at 1778 Pennsylvania Avenue, N.W., Washington, D. C. Captain David Smallhorst who replaced Captain Klassen in the past, has been transferred to other duties with the Sanitary Corps, Army of the United States.

RECRUITMENT OF NURSES PASSES QUOTA

The National Nursing Council for War Service, New York, recently announced that the quota of 65,000 new student nurses set for the year ending in July had been exceeded by more than 500 enrollments. Gains during the last 6 months were due, according to the announcement, to the momentum gained by recruitment for the U. S. Cadet Nurse Corps, undertaken jointly by the U. S. Public Health Service and the Council, and the integrated efforts of the recruitment committees of state and local councils for war service.

According to Lucile Petry, Director of the Cadet Nurse Corps, renewed efforts will be necessary during the coming school year to increase the housing facilities of schools of nursing in order to accommodate 60,000 new students, the quota for 1944-1945, to provide instructional personnel, and to increase further the number of affiliations necessary for adequate clinical training. She points out that hospitals were running as much as 35 per cent

ahead of last year in number of patients and that the Army Nurse Corps had set a new ceiling of 50,000 nurses for the year 1945. The need for student nurses, she said, was still urgent.

AMERICAN HOSPITAL ASSOCIATION TO STUDY NATIONAL HOSPITAL RESOURCES

The American Hospital Association, Chicago, has announced the appointment of Dr. Thomas S. Gates, President of the University of Pennsylvania, Philadelphia, as Chairman of the Commission on Hospital Care of the Association which has been set up to make a thorough study of present hospital resources and to provide a survey upon which to base future expansion and distribution of facilities. The American Hospital Association has undertaken this study as an effort in post-war planning and in the belief that careful research in the present resources will permit an estimate of future expansion and will assist in extending hospital facilities to each member of the community. The study is being financed in the amount of \$105,000 by the Kellogg Foundation, the Commonwealth Fund, and the National Foundation for Infantile Paralysis, covering a 2 year program. Nationally known industrial, labor, education, political, and agricultural leaders will complete the 20 member commission.

ILLINOIS STATE-WIDE PUBLIC HEALTH COMMITTEE

Governor Dwight H. Green of Illinois recently appointed Benjamin Wham of Winnetka, Ill., to succeed Frederick Woodward who has resigned as Chairman of the Illinois State-wide Public Health Committee, an organization of some 4,000 citizens interested in the development of more adequate local public health services throughout the state. Mr. Wham, senior partner of the law firm of Wham, Rose & O'Brien,

in Chicago, is a past president of the Illinois State Bar Association, vice-president of the Chicago Crime Commission, a member of the House of Delegates of the American Bar Association, and a leading participant in numerous civic activities. He has taken an active interest in the work of the Illinois State-wide Public Health Committee since its creation in June, 1942.

The committee was organized as a result of the Illinois public health survey made in 1942 by the American Public Health Association, at the request of Dr. Roland R. Cross, State Director of Public Health, and with the approval of Governor Dwight H. Green. Under the chairmanship of Mr. Woodward, and co-chairmanship of Mrs. Guy A. Tawney of Urbana, it pushed the passage by the state legislature in 1943 of the Searcy-Clabaugh law which now empowers interested Illinois counties to establish and maintain full-time local public health departments. Several county affiliates of the state-wide committee have since been conducting educational campaigns for the establishment of such official local health departments under the new law. The state-wide committee has rendered assistance in these local projects through its Executive Secretary, Mrs. Fred P. Cowdin of Springfield. Mrs. Cowdin and Mrs. Tawney will continue to serve the committee.

NEW YORK CITY BOARD OF HEALTH
RELAXES COMMUNICABLE DISEASE
RESTRICTIONS

On July 11 the New York City Board of Health amended the Sanitary Code for the city relating to isolation of persons affected with meningococcus meningitis and poliomyelitis. According to Commissioner of Health Ernest L. Stebbins, M.D., this action was taken in order to conform with modern public health procedures. In both of these

for 14 days. It will from now on be required until the temperature has reached normal. The Board of Health also removed restrictions which required exclusion of contacts to these diseases from school or work.

These amendments as adopted by the New York City Board of Health parallel the action taken at the recent meeting of the Public Health Council of the New York State Department of Health and are in line with the recommendations of the joint Technical Advisory Committee for the Care of Patients with Anterior Poliomyelitis for the two departments.

According to Dr. Stebbins, in the case of meningococcus meningitis, treatment with sulfa drugs and penicillin has shortened to a marked extent the time of recovery. The organisms disappear very quickly when prompt and adequate chemotherapy has been administered. In the case of poliomyelitis, public health authorities have considered that the length of the isolation period may be safely limited to the period when temperature is above normal.

The statement of the advisory group on poliomyelitis of the New York State Department of Health and the New York City Department of Health is appended.

STATEMENT OF THE ADVISORY GROUP ON POLIO-
MYELITIS TO THE NEW YORK STATE
DEPARTMENT OF HEALTH AND THE NEW
YORK CITY DEPARTMENT OF HEALTH

At a meeting held on June 7, the Advisory Group carefully reviewed all available evidence and agreed unanimously to the following:

1. That all patients in whom a diagnosis of anterior poliomyelitis is suspected should be cared for in a hospital and that these patients may be safely admitted to the general wards but that it might be desirable to separate the patients in special wards for ease in handling.

2. That it be recommended to the Public Health Council of New York State and the Board of Health of New York City that quarantine procedures in hospitals be elimi-

nated but that concurrent disinfection of all excretions be continued.

3. That all patients should be treated whenever possible under the combined supervision of the pediatrician, orthopedic surgeon and specialist in physical medicine, and that during the acute stage the patient should be kept at complete rest and disturbed as little as possible; that during the acute stage the therapeutic value of hot moist packs (or if not available, other methods of applying heat) is recognized as a great value for the general comfort of the patient in the elimination of pain and soreness where they occur, whether these occur at rest or on movement; that splints should not be used in the acute stage of the disease except in specific instances as determined by an orthopedic surgeon.

4. A complete physical examination should be made to determine the residual muscle weakness or paralysis as soon as the patient's general condition and local muscle pain or soreness has subsided. If muscle weakness or paralysis is present, reexamination is indicated at intervals of one to two weeks depending upon the severity. If there is no impairment in muscle strength within two weeks after onset, gradual increase in the patient's activity may be permitted under careful supervision. One month after discharge from the hospital the absence of muscle weakness should be verified by reexamination. The after-care of patients with muscle weakness or paralysis should be determined after joint observation by the specialists concerned.

The members of the Advisory Committee include:

Dr. Edward S. Godfrey, Commissioner of Health, New York State Department of Health

Dr. Ernest L. Stebbins, Commissioner of Health, New York City Department of Health

Dr. Philip Duncan Wilson, Chief Orthopedist, Hospital for Special Surgery

Dr. William Benham Snow, Columbia University

Dr. James L. Wilson, Children's Service, Bellevue Hospital

Dr. Tracy J. Putnam, Chief, Neurological Institute, Columbia University

Dr. R. Plato Schwartz, University of Rochester

Dr. Kristian G. Hansson, Chief of Physiotherapy, Hospital for Special Surgery

Dr. Alan deForest Smith, Surgeon-in-Chief, New York Orthopedic Hospital

LONG ISLAND COLLEGE OF MEDICINE OFFERS POSTGRADUATE COURSE IN INDUSTRIAL MEDICINE

Dr. Jean A. Curran, President and Dean of the Long Island College of Medicine, Brooklyn, N. Y., announces the presentation by the College of its Third Postgraduate Course in Industrial Medicine. This course will be given under the auspices of the Department of Preventive Medicine and Community Health during the 3 week period October 16 to November 3, 1944, and will be conducted by more than fifty leading physicians in industrial practice, authorities in allied fields and members of the faculty of the College. The main objective of the course is to provide physicians engaged in full-time or part-time industrial practice, as well as those who wish to enter this field, an opportunity to orient themselves more fully to modern procedures in the rapidly developing specialty of industrial medicine. The two previous courses in this field given by the college in the fall of 1942 and 1943 were presented as a wartime service to industry at a time when expanding production required increasing numbers of qualified physicians for industrial practice. The course this year will place particular emphasis upon post-war conditions and problems associated with the return of workers from military service. Although designed for graduate physicians, the course will be open to industrial executives, personnel workers, industrial nurses, hygienists, engineers, and to others interested in industrial health.

The program of the course has been planned by the Industrial Medicine Advisory Committee of the college, of which Dr. John J. Wittmer, Medical and Personnel Director of the Consolidated Edison Company, is chairman.

The presentation of the course will include afternoon and evening lectures and seminars at the college,

supplemented by morning clinics and demonstrations arranged in coöperating hospitals and industrial medical departments. Segments of the course will be devoted to Medical Administration in Industry, Industrial Aspects of Internal Medicine, Industrial Surgery, Occupational Diseases and Personal Relations in Industry. A unique feature of the course is the emphasis which will be given to the medical aspects of personnel problems. Lectures presented during the course will provide the basis for the *Long Island College of Medicine Yearbook of Industrial Medicine*.

Enrollment in the course will be limited to 60 full-time students and a tuition fee of \$60 will be charged for the entire 3 week course. A limited number of applicants particularly interested in specific phases of industrial medicine or with special qualifications will be accepted for admission on a part-time basis. A detailed schedule of lectures and seminars is being prepared by the college and will be available early in September. All inquiries concerning the course should be addressed to Dr. Thomas D. Dublin, Department of Preventive Medicine and Community Health, 248 Baltic Street, Brooklyn 2, N. Y.

BRITISH BIRTHDAY HONORS

According to *Science*, the King of England's Birthday Honors list includes Knighthood conferred upon Dr. Alexander Fleming, Professor of Bacteriology at the University of London, and on Dr. H. W. Florey, Professor of Pathology at the University of Oxford, in recognition of their work on penicillin. Also Knighthood on Dr. Percival Hartley, Director of Biological Standards in the British National Institute for Medical Research.

TOXIC DUSTS AND GASES

The American Standards Association announces the approval of a new stand-

ard on Allowable Concentration of Formaldehyde—Z37.16—1944, prepared by the A.S.A. Committee on Allowable Concentrations of Toxic Dusts and Gases. The American Public Health Association is represented on this committee by J. J. Bloomfield of Bethesda, Md. Copies of the standard may be obtained from the American Standards Association, 29 West 39th Street, New York, at 20 cents each.

NEW OFFICERS OF MISSOURI PUBLIC HEALTH ASSOCIATION

The new officers elected at the recent Annual Meeting of the Missouri Public Health Association are as follows:

President—Joseph C. Willette, D.V.M., St. Louis

President-Elect—William J. Dixon, Kansas City

First Vice-President—Ina Collins, R.N., Webb City

Second Vice-President—D. A. Campbell, M.D., Neosho

Treasurer—M. L. Gentry, M.D., Jefferson City

Secretary—J. Warren Smith, Jefferson City

Representative to A.P.H.A. Governing Council—W. Scott Johnson, Jefferson City

UNITED STATES-MEXICO BORDER PUBLIC HEALTH ASSOCIATION

The United States-Mexico Border Public Health Association met in El Paso and Ciudad Juarez recently and had 196 persons in attendance. A scientific program concerning the health of states and provinces on the Mexico-United States border was presented.

The following officers were elected:

President—Dr. Federico Ortiz Armengol, State Health Officer, Chihuahua

President-elect—Victor M. Ehlers, Texas State Department of Health

Vice-President—Dr. Victor Ocampo Alonzo, State Health Officer, Sonora

Vice-President—Dr. Donald Davy, California State Department of Public Health

Assistant Secretary—Dr. Adolfo Baz Dresch, Public Welfare Services, Ciudad Juarez

PERSONALS

Central States

JOHN WILLIAM HERR, M.D., of Mill-housen, Ind., has been appointed Health Commissioner of Posey County.

CHAUNCEY A. HYATT,* Chicago, Ill., Swimming Pool Sanitarian, resigned July 1, from the staff of the State Department of Public Health.

EDWIN M. IRELAND, M.D., has been appointed Health Officer of Pratt County, Kan., to succeed Ernest J. Beckner, M.D.†

THURMAN R. LAUGHBAUM, M.D.,† P. A. Surgeon, U. S. Public Health Service, has been appointed Health Officer of Geary County, Kan.

Eastern States

EDWARD M. BANGASSER, M.D., Buffalo, N. Y., has been appointed Health Officer of Lancaster, N. Y., to succeed CLARENCE B. MACKEY, M.D.

JAMES C. BOLAND, M.D.,† Binghamton, N. Y., has been appointed Health Officer of Troy.

DAVID E. FRASER, M.D., has been appointed Health Officer of Lyndonville, N. Y.

HENRY C. LAPP, M.D., has resigned as Health Officer of North Tonawanda, N. Y., a position he had held for twenty-two years. He was a member of the Board of Health for twenty-five years.

Southern States

CHARLES ARMSTRONG, M.D., Sc.D.,* of the National Institute of Health, Bethesda, Md., was among those elected to the National Academy of Sciences. Dr. Armstrong recently received the Sedgwick Memorial Medal for distinguished service in public health.

ABRAM J. DAVIS, M.D.,† Swainsboro, Ga., has resigned as Health Commissioner of Emanuel County to accept

a similar position in Richmond County.

CHARLES L. RIDLEY, M.D., Macon, Ga., Health Officer of Bibb County, has been appointed Chairman of the State Department of Public Health, Atlanta, Ga.

PAUL W. SHIPLEY† recently resigned his position as Associate Public Health Representative and Chief of Tabulation and Analysis Section with the Louisiana State Department of Health, New Orleans, La., to accept a commission in the commissioned Corps of the U. S. Public Health Service as Assistant Sanitarian (R), and has been assigned to the Mississippi State Board of Health, Division of Preventable Disease Control, Jackson, Miss., as Epidemiological Sanitarian.

DON E. WILDER, M.D., Grayson, Ky., recently resigned as Health Officer of Carter County, Ky.

Western States

PERCY F. GUY, M.D.,† Seattle, Wash., has been appointed Assistant Health Officer of King County, Wash.

IVAN C. HALL, Ph.D., formerly Professor and Head of the Department of Bacteriology and Public Health, University of Colorado School of Medicine at Denver, and for the past 2½ years Director of the Central Laboratory of the Contaminated Wound Project, Subcommittee on Surgical Infections, National Research Council, with headquarters at the College of Physicians and Surgeons, Columbia University in New York, N. Y., has been appointed Professor and Chairman of the Department of Bacteriology at New York Medical College, Flower and Fifth Avenue Hospitals, succeeding LAURA FLORENCE, M.D., who will retire in September.

* Fellow A.P.H.A.

† Member A.P.H.A.

WILLIS E. SMICK, M.D., has resigned as Deputy County Health Officer of Kittitas, Wash.

Foreign

J. M. MACKINTOSH, M.D.,† according to *Science*, has been appointed to the Chair of Public Health at the University of London, tenable at the London School of Hygiene and Tropical Medicine.

JOHN HARLAND PAUL, M.D., who has been in charge of malaria control work in Haiti, has accepted appointment as Director of the Bureau of Malaria Control of the Florida State Department of Health, Jacksonville.

GORDON CLIVE SMITH, M.D., has been appointed Medical Officer for Industrial Hygiene in the Department of Public Health at New South Wales.

SIR STANLEY WOODWARK, according to *Science*, has been appointed President of the Royal Institute of Public Health and Hygiene, London.

CONFERENCES AND DATES

American Association for the Advancement of Science—Annual Meeting and Annual Science Exhibition. Cleveland, Ohio. September 11-16.

American Congress of Physical Therapy—23rd Annual Scientific and Clinical Session. Hotel Statler, Cleveland, Ohio. September 6-9.

American Dietetic Association—27th Annual Meeting. Palmer House, Chicago, Ill. October 25-27.

American Education Week—November 5-11.

American Hospital Association. Cleveland, Ohio. October 2-6.

American Public Health Association—Second Wartime Public Health Conference and 73rd Annual Business Meeting. Hotel Pennsylvania, New York, N. Y. October 3-5.

American Public Welfare Association—Regional Conference. Cheyenne, Wyo. September 13-14.

American Public Works Association. St. Paul, Minn. September 24-27.

American Water Works Association—North Dakota Water and Sewage Works

Conference—Grand Pacific Hotel, Bismarck, N. D. September 12-13.

Western Pennsylvania Section—Roosevelt Hotel, Pittsburgh, Pa. September 13-14.

Rocky Mountain Section—Cosmopolitan Hotel, Denver, Colo. September 21-22.

American Public Works Congress—St. Paul, Minn. September 24-27.

Southwest Section—Hotels Stephen F. Austin and Driskill, Austin, Tex. October 17-19.

Missouri Valley Section—President Hotel, Kansas City, Mo. October 23-24.

California Section—Biltmore Hotel, Los Angeles, Calif. October 24-26.

West Virginia Section—Chancellor Hotel, Parkersburg, W. Va. October 26-27.

New Jersey Section—Atlantic City, N. J. November 2-4.

Four States Section—Benjamin Franklin Hotel, Philadelphia, Pa. November 8-10.

Virginia Section—John Marshall Hotel, Richmond. November 14-15.

Florida Section—Suwanee Hotel, St. Petersburg, Fla. November 16-18.

Association of Military Surgeons of the United States. Hotel Pennsylvania, New York, N. Y. November 2-4.

Biological Photographic Association—14th Annual Meeting. Binghamton, N. Y. September 7-9.

Civil Service Assembly—Conference on Public Personnel Administration. Chicago, Ill. November 1-3.

Federation of Sewage Works Associations. William Penn Hotel, Pittsburgh, Pa. October 12-14.

International College of Surgeons—Ninth Annual Assembly. Benjamin Franklin Hotel, Philadelphia, Pa. October 3-5.

National Association of Sanitarians—8th Annual Conference. Hotel Hilton, Long Beach, Calif. September 17-19.

National Chemical Exposition—Sponsored by the Chicago Section of the American Chemical Society. The Coliseum, Chicago, Ill. November 15-19.

New England Industrial Nurses Association and Institute on Industrial Nursing—29th Annual Conference. Hotel Statler, Boston, Mass. October 13-15.

New York Institute of Clinical Oral Pathology. New York Academy of Medicine. Hosack Hall. October 30.

New York State Association of Milk Sanitarians—Annual Meeting. Hotel Syracuse, Syracuse, N. Y. September 20-22.

Pennsylvania Sewage Works Association—Seventeenth Annual Conference. William Penn Hotel, Pittsburgh, Pa. October 12-14.

Surveys of Nutrition of Populations*

4. The Vitamin D and Calcium Nutrition of a Rural Population in Middle Tennessee

JOHN B. YOUMANS, M.D., E. WHITE PATTON, M.D.,
W. R. SUTTON, PH.D., RUTH KERN, AND
RUTH STEINKAMP

Department of Medicine and the Department of Biochemistry, Vanderbilt University, Nashville, Tenn.

THIS report deals with the vitamin D and calcium nutrition of the population whose general character and nutrition in respect to certain other nutritive factors have been described in previous publications.

METHODS

Dietary—The diet intake record in respect to vitamin D and calcium was obtained as previously described.¹ For the calculation of calcium intake the tables of *A Laboratory Handbook for Dietetics*, by Mary Davies (Schwartz) Rose, *The Fundamentals of Nutrition*, by Hawley and Maurer-Mast, the *Farmers' Bulletin, Rabbit Raising*, U. S. Department of Agriculture, and *The Structure and Composition of Foods*, by Winton and Winton were used.² For

vitamin D the tables used were by Booher, Hartzler, and Hewston, "A Compilation of the Vitamin Values of Foods in Relation to Processing and Other Variants."³ In each instance the value most clearly applicable in respect to season, variety, preparation, etc., was selected. In the few instances where values were lacking in these tables other sources were used, or, if no satisfactory figures could be found, arbitrary values were assigned on the basis of similarity to other foods or on similar grounds. In no cases did such arbitrary assignment of values modify the results significantly.

History and Physical Examination—A medical history and a physical examination of every subject was obtained as described in a previous report. Unfortunately there are few symptoms and signs of either calcium or vitamin D deficiency except in relatively severe and advanced deficiency states. Also, except in very young children (generally under 3 years), the physical signs

*The studies referred to herein were conducted under the auspices of the International Health Division of the Rockefeller Foundation of New York City by the Nutrition Unit of the Departments of Medicine and Biochemistry of the Vanderbilt University School of Medicine, Nashville, Tenn.

of vitamin D deficiency (rickets) are those of healed rickets, the scars or residual deformity of rickets. In the history particular attention was paid to weakness, head sweating, skeletal deformities, disorders of growth and development which might possibly be attributed to rickets or calcium deficiency, and to a prior diagnosis of rickets, tetany, or osteomalacia. A record of frequent or excessive decay or disturbances in eruption and formation of the teeth in children under 16 was included. The intake of cod liver oil or other forms of vitamin D or calcium supplement was recorded.

Physical examination paid special attention to skeletal deformities, cranio-tabes, dental development and hygiene, and physical weakness possibly associated with rickets. Rachitic deformities in older children, representing old, inactive rickets, were recorded as a matter of interest concerning previous vitamin D nutrition. They were clearly distinguished from those deformities probably indicating active rickets. Physical signs of calcium deficiency included skeletal deformities, particularly of the thorax and pelvis, seen only in rather severe chronic deficiencies, and Chvostek's sign, Trousseau's sign and similar manifestations of tetany.

Laboratory—Laboratory tests and special procedures included the phosphatase, phosphorus, and calcium concentration in the blood and x-ray photographs of certain bones. The blood phosphatase was determined by the method of Bodansky⁴ which includes a determination of the blood phosphorus. Concentration of calcium in the blood serum was determined by the Kramer-Tisdall⁵ technic. Determination of the blood calcium was included despite the belief that low values, except for a rare calcium deficiency complicating rickets, would be very few, even if there were calcium deficiency. It seemed desirable to obtain such data

for a general population in conjunction with a record of calcium intake.

The x-ray examinations included an anterior-posterior view of the hand, wrist, and lower forearm and a lateral view of the foot, ankle, and lower leg. Most of the examinations were made with the regular hospital apparatus and technics and, because the present report deals with only the usual clinical roentgenologic diagnosis of rickets, osteomalacia and demineralization (osteoporosis), the technic will not be described in detail. A few of the x-ray photographs were made with a mobile apparatus. The photographs were interpreted by one of the professional staff of the Department of Roentgenology.* In addition to the usual clinical interpretation, the density of bone as revealed in the x-ray photograph was measured by a densitometer using a photoelectric cell. This latter investigation however will be made the subject of a separate study and report.

RESULTS

In order to conserve space, tables of the dietary intake of vitamin D have been omitted because the unknown supply from ultra-violet light (sunlight) makes it difficult or impossible to determine the adequacy of the dietary portion. It is worth noting however that only 11 of 72 children 1-3 years of age were recorded as receiving as much as 100 International Units of vitamin D daily in their diets. The intake in the form of a medical supplement given to those subjects with symptoms, physical signs, or laboratory evidence of a deficiency is recorded in the discussion of those cases.

The intake of calcium according to age, sex, and race is shown in Table 1. Sixty-eight per cent of the white and 87

* We are greatly indebted to Dr. Herbert C. Francis, Associate Professor of Radiology for the roentgenographic diagnosis.

† M=Male; F=Female

per cent of the colored subjects had deficient intakes according to the recommended allowances of the Food and Nutrition Boards.* The deficiency is even more striking when the individual age and sex groups are examined. Al-

most none of the colored children were recorded as having an adequate intake, and the deficiency is most frequent in those groups with highest absolute requirements, children 10-12, boys 13-20, and girls 13-15. The group with the fewest deficient intakes is the white men (21+), more than half of whose diets were adequate in calcium accord-

* National Research Council

ing to the standard used. The intakes of those with evidence of vitamin D or calcium deficiency are discussed in detail below.

The values for the blood phosphatase activity and the concentration of calcium in the blood are shown in Tables 2 and 3. Very few abnormal values were found and these are presented in detail in the discussion of the subjects who had clinical or laboratory evidence of vitamin D or calcium deficiency. In this discussion are included the very few abnormal values for blood phosphorus. The table of the results of the latter determination is omitted.

Thirty-five subjects had clinical or laboratory evidence of vitamin D deficiency (rickets). Twelve had clinical

symptoms and signs, crainotabes (1), deformities of the chest, head or extremities (8), pot bellies (7), and muscular weakness (1), which were considered to indicate active rickets. Four were infants under 1 year, 4 were 1, and 4 were 2 years old. Five were white and 7 were colored. The x-ray showed active rickets in 3, healed rickets in 2, and was negative in 7. The blood calcium was slightly elevated in 2 (11.3 and 11.5 mg. per 100 ml. serum), and not determined in the rest. The blood phosphorus was normal in 7 and unknown in 5. The blood phosphatase activity was normal in 4 (in one it was 11.55 units), and not determined in 8. In addition to those with a diagnosis of active rickets, 54

* Twenty-five children under 1 year of age are omitted.

† M=Male; F=Female.

subjects, 36 white and 18 colored, aged 3 to 86, had skeletal deformities or dental abnormalities indicative of old, healed rickets.

Besides those with symptoms and physical signs, 11 subjects had only x-ray evidence of active rachitis. This was classed as severe in 1, moderate in 2, early in 1, mild, healing in 6 and questionable in 1. Two were older children (8 and 9), the others one year old or less. The blood calcium was determined in only the 2 older children and 1 infant. It was slightly elevated in the former (11.9 and 16.3 mg. per 100 ml. serum). The blood phosphorus was 7.3 mg. in the subject with a blood calcium of 11.9 mg., and 7.75 mg. in another. In 5 it was normal and it was not determined in 4. The blood phosphatase was 18.52 in one infant with moderately active rickets by x-ray,

normal in 3 others, and not done in 7 (6 infants and 1 child). One of the infants was receiving an adequate supplement of vitamin D, another inadequate amounts. Besides those with x-ray evidence of active rickets 4 subjects showed healed rickets by this method of examination.

Twelve children under 12 years of age, in addition to those with clinical or x-ray signs of rickets, showed a greater phosphatase activity than normal (more than 12 units). Values ranged from 12.05 to 19.10, mostly between 12 and 14 units. Only 2 of these were infants, the others were 5 to 13 years old. Males and females were equally represented and 9 including the 2 infants, were colored. Seven were from 3 families. Blood calcium concentration was slightly elevated (11.3-11.7 mg. per 100 ml. serum) in 4 of

these, normal in 3, and unknown in 5. Blood phosphorus was normal except perhaps in 1 (6.0 mg.). Only 1 subject had received any vitamin D supplement and that only for 6 weeks.

Sixty-one older children and adults had phosphatase values over 6 units. With 2 exceptions these ranged from 6 to 12 units and were proportionately more frequent in the Negroes than the whites. An interesting finding is the decidedly greater number, relatively, of males 13-15 with these higher values compared with females of the same age or compared with the males of older ages.

Only 5 subjects showed symptoms or physical signs compatible with calcium deficiency, 1 a child of 1 year and the others all adults, women 39, 44, 55, and 86, respectively. The infant had a history of recent spasms and a delayed dentition. It was breast fed with supplemental food but received no form of vitamin D. The x-ray showed osteoporosis, blood calcium was not determined, and the blood phosphorus and phosphatase were normal. The colored woman, 44, had had 14 pregnancies, gave a positive Chvostek and a questionable Trousseau's sign, and showed a doubtful osteoporosis on x-ray. Of the other women, one had had 11, one 2, and the other no pregnancies. Two had kyphoscoliosis and all showed osteoporosis on x-ray. The blood chemistry determinations were normal in 3 of the women and not done in the 4th. None were taking any form of vitamin D. Calcium intakes were 0.197, 0.245, 0.555 and 0.811 mg. daily.

In addition to those with clinical symptoms and signs, 57 subjects, 10 colored and 47 white, showed an osteoporosis on the x-ray examination. In none was the osteoporosis severe or of a grade seen in clinical osteomalacia. Of these only 16 were males, including 3 children, and 41 were females with

6 of them children. Of the 13 adult males, 9 were 40 years old or over. Thirty-three of the 35 adult women were 40 years of age or more.

Thirty of the 35 adult women had had 1 to 11 pregnancies each, 18 had had 5 or more. The calcium intake varied from 0.172 to 2.201 gm. daily, with 41 having an intake below 0.8 gm. Two subjects had taken an adequate supplement of vitamin D, one 7 months and one several weeks previously.

Blood calcium was slightly elevated in 9 (11.1-11.6 mg. per 100 ml. of serum), 8.9 mg. in 1, and not determined in 11. All phosphorus values were normal. The phosphatase was abnormal in only 2, 9.71 units in a 56 year old woman with 10 pregnancies and a calcium intake of 0.258 mg., and 8.02 units in a woman of 65 with 7 pregnancies and an intake of calcium of 0.548 mg.

Besides those with signs and symptoms of calcium deficiency or osteoporosis on x-ray examination, 14 subjects had a concentration of calcium in the blood serum of less than 9 mg. per 100 ml. They were about equally divided between white and colored, male and female. Four were children, an infant 2, and 3 boys 12, 13, and 15 years of age. Five of the adults were 50 years old or more. All of the women had been pregnant one or more times and 1 was pregnant when examined. The intake of calcium was below 0.8 gm. in 13. In 11 the blood calcium was between 8.5 and 9.0 mg. and in only 1 was it below 8.0 gm. (6.9). This subject presented no other significant findings. Blood phosphorous was 6.92 in the 2 year old child, normal in the rest. The blood phosphatase was normal in all. Only the 2 year old child had received vitamin D supplement, an adequate dose for 6 weeks.

The relation of dental structure, development, and decay to nutrition is so confused that an analysis of dental de-

fects has been reserved for a separate study. However, it may be noted that preliminary analysis shows no relation between the large amount of dental caries observed (approximately 60 per cent of all subjects) and any of the aspects of vitamin D or calcium nutrition.

DISCUSSION

Based on the number with one or more of the positive signs of vitamin D deficiency (symptoms and physical signs, x-ray changes, and high phosphatase values), the incidence of this deficiency in the total population is very low, about 2 per cent. Such a calculation ignores, however, the fact that it is impossible under the condition of the survey to detect and distinguish slight vitamin D deficiency in adults and that this deficiency is confined in a practical sense to early childhood. Considered as rickets, a characteristic and well defined disease of vitamin D deficiency in childhood, the incidence will again depend on the age limits established. The inclusion of all ages for which the childhood limits of normal phosphatase concentration apply (12 units), means the inclusion of a large number of subjects in an age period beyond that in which active rickets ordinarily occurs. On the more usual basis of ages up to 3 years, rickets was found in 23 of 94 subjects (24 per cent), an incidence similar to that often estimated for such a population. Even 24 per cent may not portray accurately the incidence of *active* rickets. Of the 12 subjects with symptoms and physical signs, only 3 had x-ray evidence of active rickets. Though the x-ray is not infallible it is well known that it is often impossible to determine active from inactive rickets of a mild grade by physical examination alone. Even the x-ray cannot detect the mildest grades of rickets or distinguish minimal activity. Unfortunately, in the present

survey the infrequency of the determination of phosphatase activity in the youngest subjects made this test of little help, and its value is poorly determined. Of the 3 subjects with rickets on physical examination and positive x-ray signs, 2 had no phosphatase determination. Phosphatase was normal in the other. In the 2 with physical signs and an x-ray diagnosis of *healed* rickets the phosphatase concentration was normal in one and borderline in the other (11.55 units). Of the 7 with physical signs and a *negative* x-ray, the phosphatase was normal in 1 and not done in 6. In the 11 subjects with x-ray evidence of rickets and no physical signs the phosphatase was determined in only 1. In that one it was abnormally high (18.52). Only 2 children in the age group under discussion had elevated phosphatase as the sole evidence of rickets.

Despite, however, the inability of physical examination or even x-ray to distinguish accurately active from inactive or healed rickets it is probably advisable to include both in a survey involving the age period of greatest susceptibility (up to 3 years) because they would give a fairer picture of the actual incidence of mild rickets in a group in which mild rickets is rapidly "cured."

The subjects over 3 years of age with abnormally high phosphatase activity are of particular interest. Although they have been classed with the vitamin D deficient (rachitic) group, the significance of high values in these older children is not clear and it is possible that they do not indicate such a deficiency. It is possible that they reflect osteomalacia, the manifestation in adults of vitamin D or calcium deficiency, or perhaps more often a combination of both. However, if this is the explanation, in no case were the deficiencies sufficiently severe to cause x-ray evidence of osteomalacia, or a

hypocalcemia. Blood serum calcium values in fact tended to be a little elevated.

Only 7 of the 35 subjects with some evidence of rickets were given any vitamin D supplement. For some of them the dosage was inadequate, and others had begun it only recently, apparently after the appearance of the disease. The practical necessity of giving vitamin D supplements to meet requirements and prevent rickets in early childhood is generally accepted, and the lack of such a supplement would of itself seem strong evidence of a vitamin D deficiency. However, lack of such a supplement was just as frequent in those who had no evidence of rickets. Another factor in the occurrence or non-occurrence of rickets is the rate of growth and the state of nutrition with respect to other factors, an influence which must be taken into account in this study. It is interesting therefore that although a disproportionate number with signs of rickets were Negroes, less than one-third of the total number belonged to the low income group.

Actual calcium deficiency seems to have been very uncommon. Although 76 subjects had some of the changes which might represent such a state, it is very unlikely that more than a few of these actually had a deficiency, in spite of the frequency of deficient calcium intakes as judged by the standards used. Three subjects, the infant with spasms, the 44 year old woman with the positive Chvostek and questionable Trousseau's sign, and the 29 year old man with a blood calcium of 6.9 for which no other cause was apparent, probably had such a deficiency. It is also quite possible that 2 of the 3 women with the spinal deformities can be included and perhaps the 2 women with osteoporosis and an elevated phosphatase. It should be emphasized however that calcium deficiency alone is unlikely.

In the majority of these 76 subjects the only evidence of calcium deficiency was an osteoporosis, detected on x-ray examination. Osteoporosis of a grade exhibited by those subjects is believed to occur in old age and in women at and after the menopause, unrelated to calcium deficiency. Most of our subjects with osteoporosis fall into one of these two groups and, in the absence of stronger evidence to the contrary, one is forced to conclude that few if any of them had an actual calcium deficiency.

Unfortunately for its detection calcium deficiency is not accompanied in man by a hypocalcemia except in severe or very chronic cases. Even the finding of a concentration of calcium slightly below the arbitrary lower level of normal is often without significance, and it is likely that for the majority of the subjects with values below 9 mg. per 100 ml. the finding is of no physiologic significance. Only for the 2 or 3 lowest values may there be an intimation of actual calcium deficiency.

SUMMARY

Certain features of the nutrition of a rural population in middle Tennessee in respect to vitamin D and calcium are presented. These include the individual dietary intake of calcium, the findings of a medical history and physical examination, the concentration of calcium and phosphorus and the level of alkaline phosphatase activity in the blood, and the results of an x-ray of the examination of bones of the wrist and forearm, ankle, and leg.

A high incidence of a deficient intake of calcium, on the basis of recommended allowances of the Food and Nutrition Board, was observed, but clinical or laboratory evidence of calcium deficiency was uncommon. Clinical or laboratory evidence of rickets (including x-ray) was found in about 25 per cent of the subjects under 3

years of age, but in some of these the disease was probably healed. Despite some x-ray evidence of osteoporosis and an elevated phosphatase activity in a few older children and adults, instances of probable deficiency of vitamin D, or combined vitamin D and calcium, were very few among these subjects.

Memorial to Dr. C. C. Young

A concurrent resolution adopted by the House and Senate of the State of Michigan commends the achievements and honors the late C. C. Young, D.P.H., who for many years was Director of the Bureau of Laboratories of the State Department of Health in Lansing. Included in the memorial is the following resolution:

"That the Michigan Legislature convened in Extraordinary Session . . . on

behalf of the people of the State of Michigan, in order that the memory of Dr. C. C. Young shall be forever preserved, hereby designate that the Administration Building of the Michigan Department of Health shall hereafter be known as the 'C. C. Young Public Health Laboratory.'"

The resolution also provides that a suitable plaque be erected in the laboratory.

Early Days of the Public Health Education Section

H. E. KLEINSCHMIDT, M.D., F.A.P.H.A.

American Red Cross, North Atlantic Area, New York, N. Y.

A HALF century of American Public Health Association history unfolded before its Section on Health Education and Publicity was born. The infant arrived not with a silver spoon in its mouth; in fact its early days were precarious ones. Once these were successfully past, the lusty youngster showed vitality and grew rapidly and now numbers 806 members, of whom 137 are Fellows. Its name meanwhile has been changed to the Section on Public Health Education.

The delegate to the Association's Annual Meeting in 1920, who came because he was starved for a bit of nourishment that would help him grow up to his job of health education, would have to shop from section to section to satisfy his hunger. He might even return home still hungry and without having been warmed by the companionship of kindred spirits who were equally famished. There was a growing number of such members of the Association whose chief interest was health education, in the very bosom of the public health family they felt lost. Our hypothetic delegate was free as in a cafeteria, to choose from the programs of the eight sections into which the Association was then divided; but what choice did he have? He was welcome to listen to a paper on "Sanitation in Bakeries," or, if he were not particularly bread-minded, to a paper on "Hookworm in California Gold Mines," in the Industrial Hygiene Section. From there he had the privi-

lege of wandering to the meeting of the Laboratory Section to hear a treatise on "Detection of Manural Pollution in Milk," another on "Standardization of Botulism Antitoxin," and if he was still awake, a paper on "The Helpless Narcotic." The Food and Drug Section offered him a dissertation on "Evaporation of Fruits and Vegetables," and Vital Statistics tried to lure his attendance by offering a paper on "Birth and Death Certificates as Legal Evidence." Surely his pulse quickened when he discovered that in the Child Hygiene Section he would hear about "Mothercraft Instruction for School Girls." He might gather some crumbs there, and he wrote on his cuff (the detachable kind) the time and place for the meeting of the Industrial Hygiene Section where he was promised a paper on "Health Education in Industry."

Among these scattered but fairly numerous forgotten men and women who were stirring restlessly there was one catalyst, Evart G. Routzahn, who today is held in endearing memory by the Section as its father. Routzahn found a responsive champion in Dr. William F. Snow, who in turn interested Dr. Lee K. Frankel, Past President of the Association, in the project of organizing a health education group. Routzahn had many friends and a persuasive personality and soon there was a well-voiced demand for recognition of those who needed help in health education practice. At the jubilee meeting of the Association, cele-

brating its fiftieth anniversary and held in New York, November 14-18, 1921, there appeared for the first time a special section program devoted entirely to health education. Permission to form a provisional section had been granted by the Governing Council, and the program was held under the Section's auspices. The purpose of the session was described in the printed program in these words:

This session aims to bring together the public health workers who are interested in popular health education and publicity. The aim will be to take some first steps toward frankly facing the practical problems which need to be solved in order to secure the results desired from the millions of pieces of printed matter that are being distributed, the great number of addresses, and the increasing use of a growing variety of educational material.

That first session verified the belief and contention that potential interest existed; it was well attended and the discussion was lively. The Symposium on Motion Pictures was conducted by Mr. Routzahn as chairman, and six persons participated. The second session was devoted to a symposium on How To Further Progress in Health Education and Publicity, led by Dr. Snow, and again there were several energetic participants. The spontaneity of these meetings contrasted favorably with the usual formality of other Section meetings and this at once attracted the younger members of the Association who felt no particular allegiance to a given Section and, perhaps, caused some lifting of eyebrows of older members. At the ensuing meeting of the Governing Council held a month later, an influential member reported favorably on the Section, stated that it had attracted 175 persons, and recommended that the Section be continued on probation, so to speak, for another year.

The following year, 1922, the Association met in Cleveland. Dr. Lee K.

Frankel was chairman and B. R. Rickards, secretary of the trying-to-be-born section. Again progressiveness was reflected in the unique program. It was something of an innovation to invite non-members of the Association, men not identified with public health, to take a leading part in the program, but that is what the Section did. William Feathers and William Henry Baker, both eminent in the fields of typography and publicity, conducted at the first session what was called a "Clinic on Printed Matter." Samples of health publications had been selected for review, analysis, and criticism. Copies had been supplied to the audience and the two experts analyzed one after another of the pamphlets from the standpoints of copy, form, and typography. That was a lively and instructive session and stirred much comment which led to the improvement of printed matter (and how sorely that was needed!), for the authoritative words of men who were in no way connected with public health and who could view the products objectively, carried weight. So successful was this technic that "clinics" continued to be the popular type of program for the Section for years after; and they have not yet lost their attraction-power and interest. The second session was devoted to a symposium on newspaper publicity. Once more permission to conduct a session on health education the next year was granted.

At the Boston meeting, held in 1923, there was another Clinic on Printed Matter, under the chairmanship of Evert G. Routzahn and the leadership of Phillip S. Platt, and there was also a luncheon session at which Motion Picture Programs and Problems were discussed. As usual, the attendance was good, so good that those standing in the doorway attracted others who were curious to learn what the excitement was about, and thus spread the

fame of the Section. The big news event however, was that the Section had been accepted in full status—at last the lusty urchin was weaned and legitimatized! That year the Fellowship plan was introduced and only Fellows were eligible to hold office—which put a strain on the Section for, while its membership had grown somewhat, only a few were Fellows. We did, however, manage to assemble a slate, and duly elected H. E. Kleinschmidt, Chairman, B. R. Rickards, Vice Chairman, and Marjorie Delavan, Secretary. With high hopes we cheered ourselves and looked forward to the next meeting.

Though now properly recognized and with representation on the Governing Council, the Section realized full well that only struggle would keep it alive. Before leaving the Boston meeting the half dozen of us who were carrying the responsibility resolved that we would employ the shining hours until the next meeting by building up the membership, by trying to serve the members, and by planning our next meeting long in advance. The officers were widely scattered—Albany, N. Y., Lansing, Mich., and Toledo, Ohio; but the mail served us well and in our travels we did manage one or two visits. Meanwhile, Routzahn in New York saw to it that readers of the *American Journal of Public Health* were not neglected, and from his office, bits of colored paper with cryptic messages, passing thoughts, helpful hints, fluttered to our several desks. Sir William Osler always kept a package of post cards handy on which he jotted brief notes to his friends on the spur of the moment—and what a rich source of information these cards were later when they were collected by his biographer! Routzahn used memorandum pads of various hues and a typewriter that seemed to have no punctuation marks. What would you make of a pink slip

coming in the morning mail like this:

HEK

Smith wants help on movies

Bananas are being advertised as health food—true?

Send Jones ideas on newspaper leads

EGR

Routzahn's telegraphic confetti was the subject of good-natured banter, which he enjoyed; but that his memoranda commanded attention and stimulated us to act was self evident.

At the Association's meeting held in October, 1924, at Detroit, the Section, like a small boy at a family party, really made its existence known. Besides its two sessions it joined with the Vital Statistics Section in a third meeting, and sponsored two luncheon meetings and a dinner.

For the third time a clinic on printed matter was conducted, testifying to the popularity of this type of program. But the session that was long remembered by the many who crowded into the room was one on Newspaper Publicity. This time, two outsiders, E. G. Burrows, of the Department of Journalism of the University of Michigan, and Lee A. White of the *Detroit News*, and one speaker long identified with health education, Philip P. Jacobs, led the symposium. A note printed in the program stated: "The audience will be supplied with newspaper articles discussed by the speakers." When this session was planned we wondered how to furnish the audience with clinical material, which is a necessary part of the clinic technic. Like medical students who crane their necks vainly to see what the surgeon is doing, our audience would not be able to follow the clinicians as they analyzed the subjects before them unless they had copies at hand. Furthermore, one value of the printed matter clinic was that the audience accumulated samples of good and poor pamphlets, with the clinician's comments, and carried them home for

guidance in their future printing plans. How could clinical material consisting of newspaper articles be furnished? The difficulty was solved with the help of Mr. White. He promised that if we would collect clippings of the articles we wished to have examined, he would have them reprinted in standard newspaper form by his newspaper, *The Detroit News*. To Marjorie Delavan goes the credit for having assembled from all parts of the country a fine assortment of short news articles on health which had actually been printed, and these were arranged on a newspaper page under the masthead of the *News*. A plentiful supply was printed. The evening before the session, a few daredevil members of the Section peddled these sheets in newsboy fashion among the delegates, in the hotel lobby and at the entrance to the ball room where guests congregated for the Association's annual dinner. It was not a very dignified performance but our customers were amused and even some venerable Fathers in Israel smiled tolerantly at the adolescent antics of this new Section—well, they were the “publicity boys,” and why shouldn't they practise their trade even at a serious conclave.

Next day our assembly room was crowded with eager listeners and with a liberal sprinkling of old-timers from other sections who came to see the fun. All three speakers did a superb job; once again the Section had proved its reason for being—it was established and feeling its oats. A few more Fellows had cast their lot with the new Section and there was little difficulty in finding able candidates for office.

Like other Sections, ours was given the privilege of occupying a department in the monthly *Journal*. Routzahn was appointed editor, and filled the columns with short items collected from everywhere—a new set of posters put out by the Blank Health Department, a novel stereopticon device, quotations

from a telling speech, source material on this subject and that. It meant, undoubtedly, that he spent much of his time collecting and classifying such material and writing many letters. His zeal in keeping in touch with health education activities all over the country was amazing.

Today Health Education Headquarters has become an established institution at the Association's Annual Meeting. There the novices and the veterans congregate, and there they find an abundance of material, all neatly indexed and displayed, with attendants in charge always willing to assist the searcher for ideas. Posters, booklets, exhibit devices, catalogues—a complete department store of health education materials and methods. This too was Routzahn's creation. And always, Mary Swain Routzahn was so closely associated with Evart that it became customary to speak of “The Routzahns.”

* * *

At the Ninth Institute on Public Health Education, held in October, 1942, and attended by 322 health workers, Professor C.-E. A. Winslow said: “The Health Education Institute is a most remarkable institution and it is a great pleasure to watch its progress from year to year. . . . It is fascinating to see its scope widen and deepen.”

That the Institute has won the respect of public health leaders is a tribute to the Public Health Education Section which created and nurtured it at a time when the Section was still weak. More than one public health veteran has expressed astonishment when, engrossed in other affairs, he accidentally discovered for the first time perhaps, the vigor and exuberance of this offspring of the Section. The records of its origin are scanty, and I am indebted to several friends who have aided my memory in reconstructing this sketch.

When the Health Education Section was groping its way in the late 20's, some of the Fellows of that Section felt that it was not enough merely to plan an annual program but that it should develop some means of helping the members to become better craftsmen in the art of health education. One suggestion made by Dr. Iago Galdston was that a definite course of instruction be provided in which the philosophy, art, and technic of health education would be taught. At the time there were few opportunities for a student to acquire such instruction in universities or schools of public health, and the worker already engaged who felt the need of a practical postgraduate course had simply nowhere to turn.

Galdston pointed out that from the membership of the Association itself, could be drawn specialists in a variety of skills such as no university could provide; and that an Institute would bring the school to the student without obligating him to sacrifice much time from his work. It was thought also that an Institute would help the Section to define more clearly its objectives and functions, for health education was a sprawling terrain with indefinite borders and unexplored areas. Finally, an Institute held in connection with the Annual Meeting of the Association, would be a means of reaching many health workers who seldom had opportunity to confer with more experienced colleagues. Since the Association's meeting was held each year in a different locality and attracted many attendants from nearby, each Institute would bring a short course to those who did not commonly enjoy the privilege of travel. It was not the purpose to duplicate the Section program, though it was difficult for some to see how that could be entirely avoided.

Galdston's suggestion was considered by the Council of the Section but no immediate action was taken. He per-

sisted however, and after some four years the Council appointed a committee to evolve a plan. This committee, consisting of Iago Galdston, Evart G. Routzahn, and H. E. Kleinschmidt, met early in 1932 and several times thereafter. It soon developed that the purpose of the Institute was not entirely clear even yet, for there was at first difference of opinion as to whether the course should be an authoritarian one in which the leaders would expound known facts and tested procedures, or a discussion outline for the exchange of ideas on new and not yet established methods, and on more or less technical questions. The former would be in the nature of an academic course, somewhat elementary and led by recognized leaders; the latter, more nearly of a research character, would be exploratory, discussive, critical, and of value primarily to those who had already attained a degree of mastery by reason of experience. To say that one method was of the "academy," and the other of the "university" type would be over-simplification, but at any rate, there was something favorable to be said for both.

Health education was attracting many new practitioners into its ranks and many of them were without much experience. To assist them in acquiring skill was a worthy enterprise. On the other hand, a considerable number of workers had already mastered the elements of health education and felt the need of group exploration; and that too would be of value to all, presumably, for new areas would thereby be discovered which would be for the common good. In the end, it was agreed that as a guiding policy it would be better to plan the Institute for those who wished elementary training.

Important as it seemed to the planning committee to establish a definite policy, the difficulty of actually living within it in practice became apparent

when the program was formulated and the sessions were held. As a matter of fact, the Institute partook of both methods, didactic and exploratory. In the announcement it was stated that:

The purpose of the Institute is to provide instruction in the content and methodology of Health Education to a limited number of persons actively engaged in Health Education. The students whom it is desired to attract to the Institute may or may not have had training in Health Education in one or the other of the few institutions where it is available. They may have had a little or considerable experience. They may devote all their time to this work or it may be merely one of several activities. In any event, Health Education is for them a major preoccupation and they must from time to time formulate programs of activities in Health Education and carry them through.

The first Institute was launched with fine enthusiasm and some misgiving. (By the way, the circular which announced the new venture was one of the handsomest pieces of printed matter ever issued by the Association.) The attitude of the Association was none too encouraging for, while authority to hold the Institute was duly granted, no great enthusiasm was manifested by the Association's governing body. However, the President of the Association in 1932, Dr. Louis I. Dublin, was energetic in his support and earnestly urged attendance, and the staff of the Association was more than helpful. A fee of \$5 and registration in advance were required of all students and this, it was feared, might be a deterrent. When the meeting opened, however, great numbers of unannounced students presented themselves in addition to those who had registered, and the quarters provided for the meeting proved entirely too small.

The staff of the Institute consisted of the following persons:

Iago Galdston, M.D., *Director*
Bertrand Brown
Evert G. Routzahn
Mary Swain Routzahn

Clair E. Turner, Dr.P.H.
W. W. Peter, M.D.
Ira V. Hiscock
H. E. Kleinschmidt, M.D.
George C. Ruhland, M.D.
W. W. Bauer, M.D.
Raymond S. Patterson, Ph.D.

This staff made careful preparations and planned to avoid duplication as much as possible. What the staff set out to do is evidenced by the program:

FIRST SESSION

Discussion of the instruments employed in Health Education; pamphlets, weekly and monthly publications and bulletins, charts, posters, health talks and radio talks; their special utility and their limitations.

SECOND SESSION

The responsibility of the health educator for the authenticity of his material. How to go about securing dependable information to present on the items selected, to the indicated audiences, and through the preferred media. Tapping authoritative sources. The coöperation of the medical profession.

THIRD SESSION

How to formulate a program of Health Education suitable to the community. How to determine the allocation of staff, money, and effort. This problem will be considered from the viewpoint of both the official agency, that is, the department of health, and of the voluntary agencies.

FOURTH SESSION

The avenues through which the program might be formulated; the population at large, special groups, schools, primary and secondary, teacher training organizations, work shops and work places, commercial organizations, etc.

It was a stimulating meeting, though not without its faults. Very soon after assembly it became apparent that the experience levels of the members of the group were of wide divergence, and this made it impossible to keep the discussion always on a common level. For each session there were a chairman, a discussion leader, and a discussor. Interruptions from the floor were invited, which privilege was freely utilized, and therefore it became impos-

sible to control the direction of the discussion. My recollection is that there was considerable wandering from the topic. But not once during those three tightly packed days did interest flag, and it was generally felt that the Institute had vividly demonstrated its need and value. After that trial experience there was no further question about repeating the effort. In succeeding Institutes the student group was divided into sections, each dealing with a different topic. At the final general session reporters summarized the proceedings of each section, so that all might share at least the more important highlights. In subsequent years, new problems have arisen, the charted course has been altered from time to time and new leaders have come to the fore—but that is another story.

* * *

From the *American Journal of Public Health*, June 1939:

"Members of the Public Health Education Section of the American Public Health Association deeply mourn the loss of their leader and friend, Ewart G. Routzahn. It is almost impossible for us to think of the Section without him, for it was his per-

sonality that gave it zest and color. At a time when only a scattered few were giving serious thought to health education as a specialty of public health E G R saw the advantage of banding such workers together. He nursed the foundling section, laid on the doorstep of the American Public Health Association, until it was accepted as a lusty member of the public health family. All through the years he guided its stumbling gait and, happily, he enjoyed the satisfaction of seeing his child grow sturdy and respected.

"Though E G R never sought honor nor office, both were thrust upon him and he carried them well. For the sheer love of the cause he labored for its well-being. Each month his cryptic paragraphs in the *Journal* stimulated us; many of us turned first to his pages. Annually his exhibit was the rallying place of all loyal members of the Section, and many a youngster and veteran in the field of health education found treasure there. To E G R we turned often and never in vain. With the advice he gave there was always a glint of humor, with his service always a beaming smile. His criticism, eagerly sought, was always penetrating, but never with a sting. Mostly we loved him for his friendliness—for his bubbling good will.

"We thank God that the bench mark E G R is indelibly impressed upon the Public Health Education Section. Time, which mellows sorrow, will never efface that bench mark. We who worked, and planned, and laughed with him have been enriched by the comradeship, and that wealth grows more precious with his passing."

Rheumatic Fever in Cincinnati in Relation to Rentals, Crowding, Density of Population, and Negroes

ARNOLD G. WEDUM, PH.D., M.D., AND
BERNICE G. WEDUM, M.D.

*Department of Bacteriology, School of Medicine, University of Colorado, and
Colorado General Hospital, Denver, Colo.**

RHEUMATIC heart disease is now the first cause of death among children aged 10 to 14, and is second only to tuberculosis at ages 15 to 25.¹ Despite the importance of this disease its cause is not known and its epidemiology is not completely established. Epidemiological thought in the past has been influenced by the early English report² that rheumatic fever was an affliction of the artisan class, and not of the impoverished. However, all authorities do not agree with this view, and Glover³ expresses his opinion as follows: "The incidence of acute rheumatism increases directly with poverty, malnutrition, overcrowding, and bad housing." The association of these conditions with rheumatic infections has been examined critically in only a few surveys covering an entire community, namely those in England,^{2,4,5} Dublin, Ireland,⁶ Australia,^{7,8} New Haven,⁹ and Philadelphia.¹⁰ The epidemiology of rheumatic infections, including the epidemiology of acute hemolytic streptococcal infections, has been well summarized by Paul.¹¹

METHOD OF SURVEY

The authors have recently completed an examination of all hospital admissions with rheumatic conditions, at all ages, in Cincinnati for the 11 year period 1930-1940.¹² There were 3,475 admissions and 2,178 cases studied in the survey (Table 1).^{*} Among these 2,178 cases there were 583 persons with a listing of rheumatic fever with or without rheumatic heart disease or chorea. Among these, home addresses in Cincinnati were available for 517. The home addresses used were given at the time of the first hospital admission during the period under study. These 517 patients had acute rheumatic infections, most of them with joint symptoms. All of them were not necessarily initial infections. It was believed that these acute cases would provide the most significant epidemiological data. All persons who had rheumatic heart disease without rheumatic fever, and all persons with uncomplicated chorea were omitted from the socio-economic analysis reported at this time.

Through the courtesy of Dr. Floyd P. Allen, Director of the Research

* The material for this paper was collected when the authors were associated with the Department of Bacteriology, University of Cincinnati College of Medicine, The Max Stern Heart Station for Rheumatic Heart Disease, and Children's Hospital, Cincinnati, Ohio.

* It should be noted that a distinction has been made between persons, cases, and admissions. One case represents one hospital's records on one person, although that case may include one, two, or more admissions

TABLE 1

*Cases of Rheumatic Infections Admitted to Cincinnati Hospitals from
January 1, 1930, to December 31, 1940*

	Number		Cases Utilized * in this Socio-Economic Analysis
All rheumatic heart disease	1,770		
Rheumatic heart disease with rheumatic fever and subacute bacterial endocarditis		9	9
Rheumatic heart disease with subacute bacterial endocarditis		51	
Rheumatic heart disease with rheumatic fever and chorea		8	8
Rheumatic heart disease with rheumatic fever		312	312
Rheumatic heart disease with chorea		52	
Rheumatic heart disease, uncomplicated		1,338	
Rheumatic fever without rheumatic heart disease	254		
Rheumatic fever with chorea		7	7
Rheumatic fever, uncomplicated		247	247
Chorea, uncomplicated	154	154	
Total	2,178	2,178	583

* in so far as addresses were available (517 of the cases)

Division, Cincinnati Public Health Federation, the authors were able to locate each home address in its proper census tract in the city. Dr. Allen has also kindly supplied the following information for each census tract:

1. Median monthly rental, 1940.
2. Per cent of occupied dwellings with 1.51 or more persons per room, 1939-1940. (This served as an index of crowding.)
3. Per cent of dwellings occupied by persons of a race other than white, 1939-1940. (Essentially an index of Negro population.)
4. Persons per net habitable acre, 1940. (This was taken as an index of density of population.)

There is a difference between *crowding*, or persons per room, and *density of population*, or persons per acre. The former is more important epidemiologically. The latter may simply be the result of many apartment houses or private homes close together.

DISTRIBUTION OF RHEUMATIC FEVER BY CENSUS TRACTS

A graphic presentation of the distribution of rheumatic fever in Cincinnati is given in Figure 1. A few words of explanation are necessary in this connection. There are 107 census

tracts. Four of these were omitted for reasons as follows:

1. C. T. 32 includes an Orphans' Home and the Cincinnati General Hospital. Four of the 5 cases occurred among the inmates or professional staff of these two institutions, and the home addresses were therefore considered inadmissible.

2. C. T. 59 had only one case in 11 years, but the sparse population caused the annual incidence to appear to be more than 10 cases per 100,000.

3. C. T. 85 had only 3 cases in the 11 year period, also in an area of sparse population, so its incidence likewise appeared to be more than 10 per 100,000.

4. C. T. 24 had a median rental of \$16, 17 per cent crowding, 57 persons per habitable acre, and 11 per cent Negroes, but an annual incidence of only 3 cases of rheumatic fever per 100,000 population. This tract is located entirely on a steep hillside (Sycamore Hill to Vine Street). It was omitted because the authors believed that the inhabitants were a selected population. No one would willingly move into or remain in the area unless in good health and able to endure the daily hill climbing. These 4 regions are indicated in Figure 1 by the number of the tract plus a question mark. The minor effect which the omission or inclusion of these 4 tracts had on the statistical significance of the data is described later.

Four other census tracts presented unusual features but were nevertheless

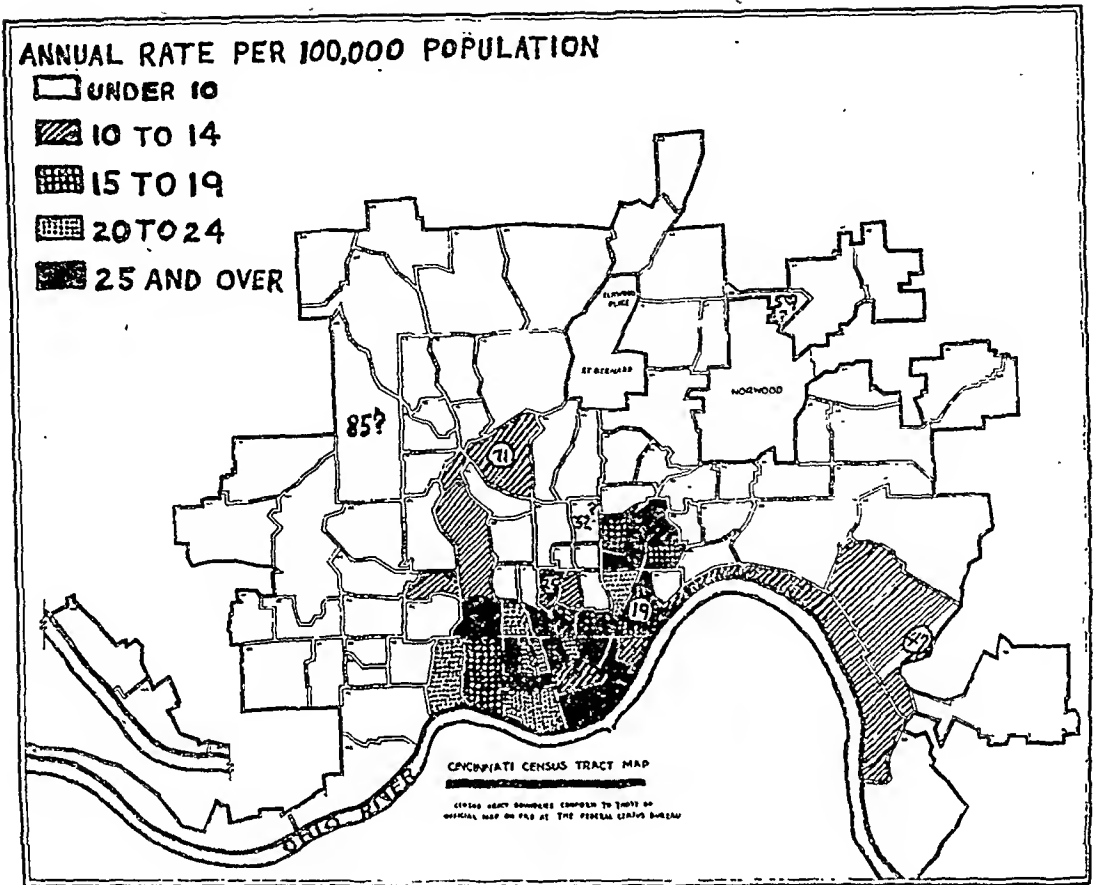

FIGURE 1—Distribution by city census tracts of 517 cases of rheumatic fever admitted to Cincinnati hospitals during 1930-1940, based on the mean annual number of cases per 100,000 population. Population based on an average of the U. S. Census of 1930 and Census of 1940. (See text regarding Census Tracts 19, 25, 47, 71 and 24, 32, 59, 85.)

included. All had an annual incidence of more than 10, but the median rentals were over \$21.65, and there was no crowding and there were no Negroes. Census tracts 19 and 47 were not economically uniform and contained homes of both the poor and well-to-do. C. T. 25 was rather uniformly an area of lower middle class homes, and C. T. 71 an area of expensive homes, but one less case in each tract would have reduced the annual incidence of rheumatic fever to less than 10 per 100,000 population.

TOPOGRAPHY OF THE CITY IN RELATION TO RHEUMATIC FEVER

Most of the patients resided in four sections of the city (Figure 1):

1. The "basin area," which is between the river front and the hills rising about a mile northward. This includes most of the slums and all of the central business district.
2. The Mill Creek Valley industrial area which runs northward in a finger-like process on the western side of the city.
3. C. T. 43 and 44 which extend eastward along the river below Columbia Parkway. This parkway is a broad concrete highway along the river above which are bluffs where part of the better residential district is located.
4. C. T. 34, 35, 36, and 37 in the Lincoln Heights District adjoining the basin area on the northeast.

The last group of tracts is easily identified in Figure 2 as comprising those marked by either cross-hatching or diagonally-slanted lines. This is not

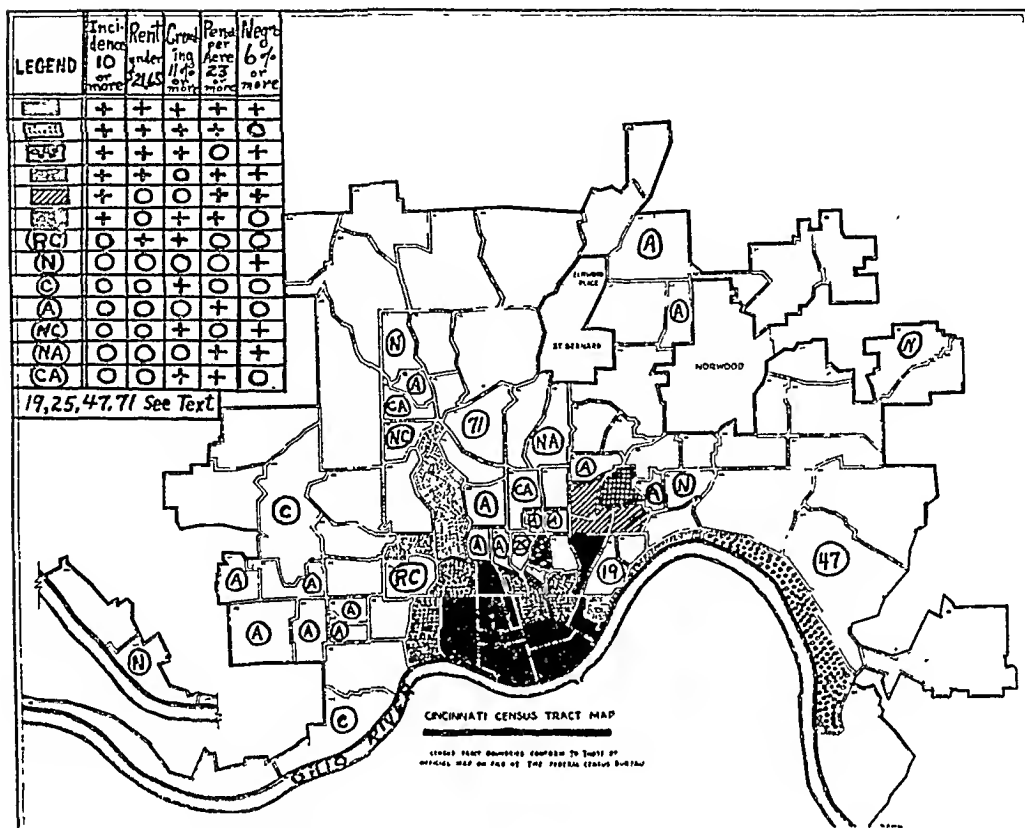

FIGURE 2—Annual incidence of hospitalized rheumatic fever per 100,000 population in each census tract, in relation to rentals, crowding, density of population, and Negro population. Letters in circles indicate characteristics of tracts so designated; thus, RC means rents low and crowded, N means high proportion of Negroes, etc.

a slum area but has a large Negro population, respectively 18, 7, 97, and 46 per cent. Furthermore, it is not a low lying or damp section but is in an elevated part of the city. This would seem to eliminate dampness and proximity to water courses as a possible major factor of importance.

SOCIO-ECONOMIC DISTRIBUTION OF RHEUMATIC FEVER

The relation of rentals, crowding within the home, density of population per acre, and Negro population to the incidence of rheumatic fever by census tracts is portrayed in Figure 2. There are some striking correlations. All 11 tracts (marked in solid black) which had low rents, crowding, dense popula-

tion, and Negroes, also had a significant level (10 or more annual cases) of rheumatic fever. All 12 tracts (stippled) which had low rents, crowding, dense population, but no Negroes (less than 6 per cent), also had a significant level of rheumatic fever. We might therefore say that the Negro was no factor, if it were not for the 4 tracts which had only dense population and Negroes. These are indicated by diagonal lines (3 tracts), or "NA" (1 tract). Three of these tracts had a significant incidence of rheumatic fever. This is consistent with the picture of rheumatic infections in Cincinnati as reported in previous papers.^{12, 13} The Negro had a higher incidence and a more severe form of this disease than

TABLE 2

Distribution by Census Tracts of 517 Cases of Rheumatic Fever Admitted to Cincinnati Hospitals During 1930-1940, in Relation to Rentals, Crowding, Density of Population, and Negro Population*

<i>Characteristics of Census Tracts</i>	<i>Annual Cases Rheumatic Fever per 100,000 Population in Each Census Tract</i>		<i>(N=1) X²</i>
	<i>10 Cases or More (C. T.)</i>	<i>Less than 10 Cases (C. T.)</i>	
1. Rental less than \$21.65 monthly	25	1	61.8
Rental \$21.65 or more	8	69	
2. Crowding 11 per cent or more	25	6	45.0
Crowding less than 11 per cent	8	64	
3. Persons per acre 23 or more	30	19	34.1
Persons per acre less than 23	3	51	
4. Negroes 6 per cent or more	16	6	19.0
Negroes less than 6 per cent	17	64	
5. Negroes 15 per cent or more	12	2	18.7
Negroes less than 15 per cent	21	68	
Rental less than \$21.65	24	1	58.9
Crowding 11 per cent or more (Omit Persons per acre and Negroes)			
6. Rental \$21.65 or more	7	64	54.5
Crowding less than 11 per cent (Omit Persons per acre and Negroes)			
Census Tracts not assignable above	(2)	(5)	
Crowding 11 per cent or more	24	2	54.5
Persons per acre 23 or more (Omit Rentals and Negroes)			
7. Crowding less than 11 per cent	2	47	
Persons per acre less than 23 (Omit Rentals and Negroes)			
Census Tracts not assignable above	(7)	(21)	

* 103 Census tracts after omission of C. T. 24, 32, 59, 85 (see text).

the white. Whether this is the result of racial susceptibility or of a different pattern of living cannot be determined exactly.

Table 2 summarizes the statistical relationship between the annual incidence of rheumatic fever and rentals, etc. The selection of (1) \$21.65 rental, (2) 11 per cent crowding, (3) 23 persons per acre, and (4) 6 per cent Negroes, was made after a trial and error method had determined that these limits gave the best correlation with the presence or absence of a significant amount of rheumatic fever. Such selection is necessary because the rental value of any one type of housing will vary in different cities and nations. Likewise the level at which crowding, density of population, or Negro population becomes important will vary somewhat in different cities depending upon other

factors such as climate and living habits. The limit of 10 annual cases of rheumatic fever per 100,000 population was also used by Hedley.¹⁰

It is evident that the order of importance is: (1) rentals, (2) crowding, (3) density of population, and (4) Negroes. For instance, there were 77 census tracts each of whose median monthly rental was over \$21.65. Only 8 of these areas had an appreciable incidence of rheumatic fever. Of 26 tracts with rental under \$21.65, 25 had a marked incidence of rheumatic fever.

According to the chi squared test, where $N = 1$, a X^2 between 3.5 and 4.0 means that the association could occur by chance alone 5 times in 100. Any larger X^2 is considered significant. For example, if the association of rentals and rheumatic fever yielded a X^2 of 10, with $N = 1$, the association could occur

by chance only 16 times in 10,000. Actually the X^2 in this instance was 61.8. All the associations in Table 2 show a high degree of significance.

Earlier in this article it was stated that C. T. 32, 59, 85, and 24 had been omitted. Inclusion of these 4 tracts in Table 2 would not seriously alter the significance of the data. In Table 2 the chi square for rentals would be changed from 61.8 to 52.7 and the other chi squares would become, reading downward in the table: 37.7, 32.9, 14.9, 17.0, 49.8, and 49.3.

SUMMARY AND COMMENT

This survey again emphasizes the importance of poverty and crowding in the genesis of rheumatic fever. However, poverty and crowding are only signposts pointing to a more fundamental epidemiological principle. It is instructive to compare the information gained by such surveys as this with what is now known about rheumatic infections in military camps in the United States. There is a comparatively high incidence of rheumatic fever in the military forces in Colorado, Idaho, and Utah. These camps are in dry* areas, removed from water courses, and at relatively high altitudes. Needless to say, poverty is no factor, and the housing, sanitation, and diet are excellent. In fact, there are only two features common both to the military forces in these states and to the impoverished civilians in areas with a high incidence of rheu-

matic fever, namely (1) crowding, and (2) inability to control the microclimate. It is not always possible for either the poor man or the military man to rest whenever he is tired, get warm when he is cold, and keep dry when it is raining. In civilian life, poverty, diet, proximity to water courses, etc., might be said to be important only in so far as they are a part of the two features mentioned, and so reduce the power of the body to resist disease.

Salmonella Isolated in Florida During 1943 with the Combined Enrichment Method of Kauffmann

MILDRED M. GALTON AND MUN S. QUAN

*Bacteriologists, Bureau of Laboratories, Florida State Board of Health,
Jacksonville, Fla.*

NUMEROUS enrichment methods for fecal bacteriology have been described in the literature, and we shall not attempt to enumerate them. (It is well known that a suitable selective enrichment is essential for the isolation of enteric pathogens from feces.

(A tetrathionate broth for enrichment of typhoid and paratyphoid bacilli was first used successfully in 1923 by Mueller,¹ who showed that it inhibited coliform organisms and allowed typhoid and paratyphoid bacilli to grow profusely. Kauffmann, 1930,² described the combined enrichment method for *Salmonella*, which consisted of the original tetrathionate broth of Mueller plus 5 per cent bile and brilliant green 1:100,000 used in combination with Kauffmann's modification of the brilliant green-phenol red agar of Kristensen, Lester, and Jurgens.³ In 1935, Kauffmann,⁴ reported the results of 10,182 feces examinations made by this method in which an increase in *Salmonella* isolations of 700 per cent over previous findings was obtained.) In typhoid isolations an increase of 30-40 per cent was noted, and in dysentery isolations an increase of 10-20 per cent. (As a result of his experiences he recommends for the examination of pathogenic intestinal bacteria, in addition to the direct streak method, the routine use of the combined enrichment method.)

Extensive investigations with this method have been reported by many European workers,⁵ by Hormaeche and Peluffo⁶ in Montevideo, by Varela⁷ in Mexico, and by others with equally favorable results. It was highly recommended to us by Dr. P. R. Edwards, Kentucky Agricultural Experiment Station in Lexington, Ky., who has also confirmed its efficacy. Since it has not, to our knowledge, been used routinely in public health laboratories in this country, the following results are reported to confirm its usefulness.

(From March 15, 1943, to January 1, 1944, 8,093 feces specimens have been examined in the central laboratory of the Florida State Board of Health at Jacksonville by the combined enrichment method of Kauffmann, and by direct streaking. A large percentage of these specimens were received from normal food handlers, the remainder were from suspected cases and contacts of enteric infections.)

PROCEDURE

Specimens were received in 1 oz. screw-capped bottles containing 10 to 15 ml. of glycerine-saline preservative. A portion of the specimen was streaked directly onto a Wilson-Blair bismuth sulfite agar (WB) plate and an SS agar (Difco) plate. About ½ ml. was placed in tetrathionate-brilliant green

bile enrichment broth. After 16–18 hours' incubation at 37° C. a large loopful of the tetrathionate broth was streaked to a brilliant green agar (BG) plate and also to an SS agar plate as the BG is not favorable for the growth of *Shigella*. Typical or suspicious colonies were picked to Kligler's iron agar (Difco) with 1 per cent sucrose added, and the procedure for identification already described by Galton and A. L. Quan⁸ was followed.

The tetrathionate broth and brilliant green agar were prepared according to the formulae of Kauffmann⁴ as follows:

Tetrathionate broth—Enrichment medium

- A. 90 ml. sterile infusion broth—pH 7.4
5 gm. sterile CaCO_3 (precipitated chalk)
10 ml. sterile 50% solution $\text{Na}_2\text{S}_2\text{O}_3$
Sterilize in autoclave
Add 2 ml. unheated solution I + KI
(20 gm. I + 25 gm. KI + 100 ml. H_2O)
- B. To 100 ml. of tetrathionate broth add 1 ml. brilliant green solution (1 to 1,000)
- C. Sterile beef bile 5%
(5% of a 10% solution of dehydrated oxgall, Difco, was used as fresh bile was difficult to obtain)

The CaCO_3 is evenly suspended by continued shaking of the mixtures.

The medium is dispensed into sterile tubes with a sterile pipette in 7–8 ml. amounts. It will keep for some time and is not further heated. We usually prepare 2 or 3 liters at one time.

Brilliant Green Agar (Kristensen, Lester, and Jurgens, modified by Kauffmann)

Per cent

Meat extract	0.5
Peptone (Difco)	1.0
NaCl	0.5
Lactose	1.0
Sucrose	1.0
Phenol red solution	4.0 (40 ml. N/10 NaOH + 460 ml. H_2O + 1 gm. phenol red)

Brilliant green
solution (0.5%) 2.5 ml. per liter
Agar 2 %

Sterilize in autoclave. Reaction should be pH 7.2–7.4.

We have found it satisfactory to pour a sufficient number of brilliant green agar plates for 2 or 3 days if they are kept in the refrigerator until used.

RESULTS

The number and per cent of *Salmonella*, typhoid and dysentery isolations obtained by the combined enrichment method and by direct streaking are shown in Table 1.

For several years, prior to the time we adopted the combined enrichment method, Selenite F enrichment, together with direct streaking to SS or DC and WB plates, was used routinely in our laboratory. The results with this method during 1942 and until March 15, 1943, are shown in Table 2 for comparison. Due to the decided decrease in the percentage of positive typhoid cultures with the combined enrichment method, we have given the results obtained with Selenite F in 1941 in Table 3, to show the much greater decrease that occurred in positive typhoid cultures before the change in methods was made. We may also add that the percentage of typhoid isolations in our blood-clot cultures has decreased from 2.07 per cent in 1941 to 0.007 per cent in 1943. The majority of our positive typhoid feces cultures come at present from repeated check specimens on the 18 to 20 known carriers in the state. In spite of this fact, Selenite F was superior to the combined method for the enrichment of *Eberthella typhosa*. We believe better results could be obtained if the tetrathionate broth were also inoculated onto WB agar, as this is, apparently, the most favorable plating medium for the typhoid bacillus.

It may be seen from the results of these examinations that our percentage of positive dysentery isolations has remained almost constant during the 3 year period. We have not, as yet, found the tetrathionate-brilliant green bile broth particularly conducive to the

Dysentery	40	0	15	40	1.8

growth of *Shigella*. Kauffmann, however, recommends inoculating the tetrathionate broth to plates after 5 and 16 hours' incubation for best results with *Shigella*. In our work we have been able to streak only after 16 hours' incubation, which probably accounts for our failure.

The results in these tables clearly demonstrate that with the combined method (Table 1), our *Salmonella* isolations have more than doubled those obtained through Selenite F enrichment. It is also significant that 20 cultures were isolated from the brilliant green agar alone. From our experience this method is far superior to Selenite F and direct streak methods for the isolation of *Salmonella*. Although the tetrathionate broth is rather time con-

suming to prepare, it is well worth the effort. Coliforms are inhibited to such an extent that frequently no growth at all appears on the BG and SS agar plates in negative cultures. *Salmonella* grow readily on BG agar. The colonies are pink or red (when appearing in pure culture), circular, convex and transparent, with even borders. *Pseudomonas aeruginosa* also develops well on this medium, but the colonies can be recognized usually by their flatness, irregular borders and purplish red color. *Alcaligenes* produces red colonies which are raised and slightly opaque. The lactose and sucrose fermenting organisms which grow on BG agar produce opaque, raised colonies, yellowish green in color. We have observed comparatively few BG agar plates on which

pink colonies were found to be slow lactose or sucrose fermenters instead of *Salmonella*, thus the picking of colonies is reduced to a minimum.

Since our results with the combined method were so favorable we began using it in our Miami branch laboratory, late last year. Reports from W. H. Miller help to confirm our opinion of its value. In $2\frac{1}{2}$ months 324 feces specimens were examined and 10 *Salmonella* isolated. During the first $9\frac{1}{2}$ months of 1943, 472 specimens were examined with the Selenite F enrichment broth and no *Salmonella* were found.

TYPES

During the $9\frac{1}{2}$ months that we have used the combined method, 107 strains of 27 types of *Salmonella* have been

isolated from 89 persons, both normal carriers and cases, as shown in Table 4.

It is notable that more cultures of *S. meleagridis* were isolated than of any other type. Strangely enough, 12 of the 14 cultures of this species were isolated from food handlers in the same community over a period of 6 weeks. It was found that the persons harboring this unusual type were not ill and that they were employed in the same canning establishment. An investigation by the county health officer has failed to reveal the source of infection. Of the other two cultures, one was obtained from a 5 year old child with enteritis, and one from a food handler. These persons lived in different sections of the state.

One new *Salmonella* type was found, which has been described by Edwards.⁹

* F.H.=food handler

^a One culture isolated from feces of a normal spider monkey.

^b *S. coli* was isolated from this patient 2 months later. Subsequent specimens failed to reveal either type.

^c Isolated from feces of two sick pigeons.

^d *E. typhosa* also isolated from the same specimen in one case which proved fatal.

^e Flexner dysentery bacilli isolated from same specimen of one food handler.

^f Sonne dysentery bacilli isolated from patient 1 month later. Neither organism was found in subsequent specimens.

He has given it the name of *S. inverness*.

The occurrence of more than one type in the same person was noted once. *S. anatum* and *S. bredeney* were isolated from an apparently normal Negress, a food handler, 27 years old. Mixed infections were encountered twice. *Salmonella oranienburg* and *Eberthella typhosa* were isolated simultaneously from a fatal infection. *S. meleagridis* and *Shigella dysenteriae* (Flexner) were obtained from the same feces specimen of a normal food handler, whose history failed to reveal previous enteric disturbance.

Approximately two-thirds of the *Salmonella* isolations were obtained from normal persons, 54 being food handlers and 6 not food handlers. A detailed questionnaire was sent to the physician in charge of each person from whom specimens were obtained, when each culture was isolated. Data have been received regarding 46 of the 60 normal carriers. The information so obtained has not revealed a single instance in which an intestinal disturbance was noted prior to isolating a pathogenic organism. This indicates that the occurrence of *Salmonella* in the stools of apparently healthy persons is not uncommon in this region.

CONCLUSIONS

In our hands, the combined enrichment method of Kauffmann has proved to be excellent for the isolation of *Salmonella* from routine feces specimens. We attribute our 164 per cent increase in positive *Salmonella* finding to the efficacy of this medium.

It did not prove as favorable for the isolation of typhoid and *Shigella*. However, with the inclusion of the following measures in our present method, more

satisfactory results could, no doubt, be obtained: (1) Inoculation of tetrathionate broth after 16 hours' incubation to a WB agar plate. (2) Inoculation of tetrathionate broth after 5 hours' incubation to an SS agar plate.

We have continued to find in Florida, a wide variety of *Salmonella* types, including all of the antigenic groups. It is possible that this occurrence is due in part to the large numbers of transient persons continually moving into and out of the state from many points of the globe.

ACKNOWLEDGMENT: The writers wish to express their appreciation to Miss Pearl Griffith, Acting Director of Laboratories, for her interest and suggestion in the preparation of this report, and to Dr. P. R. Edwards, Department of Animal Pathology, Kentucky Agricultural Experiment Station, Lexington, Ky., for identifying the cultures and reviewing the manuscript.

Epidemiological Study of Lymphogranuloma Venereum, Employing the Complement-Fixation Test

PAUL B. BEESON AND EDWARD S. MILLER

*Medical Service of the Grady Hospital and the Department of Medicine,
Emory University School of Medicine, Atlanta, Ga.*

IMMUNOLOGICAL evidence of infection with the virus of lymphogranuloma venereum is frequently encountered in persons who show no sign of the clinical disease. This brings up certain problems, such as the actual prevalence of the infection, the duration of the immune reaction, and the possibility that infection can be acquired either *in utero* or through portals other than the genital tract. Some information on these problems can be had by studying groups of people for evidence of infection. While the Frei test for lymphogranuloma has been carried out on a considerable number of people as a part of the routine work-up in many venereal disease clinics, the results obtained have provided little information on the population as a whole. With the exception of a study in Puerto Rico, by Morales and Carrera,¹ there has been no systematic application of the Frei test to a study of the epidemiology of the disease. As a survey method it is somewhat cumbersome, because it necessitates two visits with each person tested. When Rake and his associates developed a simple complement-fixation test for lymphogranuloma venereum, a method was provided which was more readily applied to epidemiological investigations. The present

report is chiefly an analysis of the results of a series of complement-fixation tests done on white and Negro clinic patients at Grady Hospital, Atlanta. It includes, in addition, the results of tests on the sera of new-born infants and their mothers, from the Colored Obstetrical Service of the same hospital.

METHODS AND MATERIAL

Kahn Test for Syphilis—The data in this article refer to the results obtained using the Standard Kahn Test, performed in the Grady Hospital laboratories.

Complement - Fixation Test for Lymphogranuloma Venereum — The technic employed was exactly the same as that outlined by McKee, Rake, and Shaffer.² The antigen used was the commercial preparation, Lygranum C. F. (Squibb). Known positive and negative sera were included as controls in each group of tests. Each serum was diluted 1-5 and 1-20 before mixing with the other components, giving final dilutions of 1-25 and 1-100. These were set up against normal yolk sac material, as well as the infected yolk sac material. The result was interpreted as positive if there was complete or almost complete fixation with

either dilution of serum in the presence of the infected yolk material. No case was encountered in which there was a prozone giving fixation with the higher serum dilution and not with the lower.

The complement-fixation test could not be interpreted in 34 of the 879 sera received from the out-patient clinics. In 7 of them the difficulty was anti-complementary action of the serum. In the remaining 27 there was fixation of complement in the presence of normal yolk sac control material. This reaction has been noted occasionally since the test first began to be used.³ It is found almost exclusively in the sera of persons with syphilis. In the present study 24 of the 27 sera which showed it gave positive Kahn reactions. Two

of the others were from young women with chronic pelvic inflammatory disease, and the third was from a young man who gave a history of chancre 3 years previously, and who had received 7 intravenous treatments immediately after he had developed the chancre. There were 14 males and 13 females in this group. Twenty-six of them were Negroes. The ages of the 27 patients were distributed fairly uniformly throughout all periods of life, including 2 infants with congenital syphilis and 4 persons who were more than 55 years of age.

Clinical Material—For the studies of the age and sex incidence 879 sera were received from persons attending the various out-patient clinics of the hos-

* No Kahn test on 17 patients

pital between November, 1942, and May, 1943. The sera were usually obtained in the course of a bleeding for a Kahn test. Since it is more or less routine to test all new clinic patients for evidence of syphilis, whatever their illness, these sera may be considered as being from an unselected group of clinic patients. Unfortunately, the clinical data obtainable from the records were often so brief, because of the minor nature of the illnesses, that it was not feasible to attempt a correlation between the results of the serologic test for lymphogranuloma and history of other evidence of this disease.

The number of white males tested was comparatively small, because many were either in military service or were in an economic bracket which made them ineligible for clinic care in a charity hospital.

RESULTS

In Tables 1 and 2 are shown the results of complement-fixation tests for lymphogranuloma venereum on the sera of 497 Negroes, arranged according to age. For comparison, the results of Kahn tests on the same persons are included in the tables. Positive tests for lymphogranuloma venereum were given by approximately 33 per cent of the entire group of colored males and females. The incidence of positive Kahn reactions was slightly lower, being 24.8 per cent for males and 28.8 per cent for females. When considered by age group it is observed that the proportion of positive tests for both diseases followed a somewhat similar pattern, being comparatively low in children under 15 years of age, but mounting rather sharply during the next decade, and then remaining at about the same level in succeeding age groups. If the data on children under 15 years of age are excluded, serologic evidence of lymphogranuloma venereum is found in 39.7 per cent of colored females and

44.8 per cent of colored males. The rates for positive Kahn tests then become 33.0 per cent and 32.1 per cent respectively.

The results of the same serologic tests on 348 white persons are presented in Tables 3 and 4. Evidence of lymphogranuloma venereum was given by 26 of 229 white females, an incidence of 11.4 per cent, and by 10 of 119 white males, an incidence of 8.4 per cent. The rates for positive Kahn tests in the same group were 7.1 per cent and 10.3 per cent respectively. Correction of these figures, by excluding data on children under 15 brings the lymphogranuloma incidence up to 12.1 per cent for females and 11.6 per cent for males, while the percentage of sera giving positive Kahn tests becomes 6.9 and 14.7 respectively. Because of the small number of white children in the present series, the results obtained in persons over 14 years of age are undoubtedly a better basis for comparison of prevalence of these diseases in the white and Negro clinic patients.

In view of the similarities in the results of serologic tests for syphilis and lymphogranuloma and since it has been claimed that persons with syphilis may give false positive complement-fixation reactions for lymphogranuloma,⁴ it seemed advisable to determine the frequency with which positive tests for both diseases had occurred in single individuals. The results of this analysis are given in Tables 5, 6, 7, and 8. These show that the similarity in incidence of positive tests for syphilis and lymphogranuloma was not due to the fact that positive tests for both diseases were largely given by the same persons. Actually the number of persons giving a positive test for one disease and a negative test for the other was in all groups considerably larger than the number of persons giving positive tests for both diseases. An additional point in this connection is the

different correlation between the two tests in the white and Negro patients. While 60 per cent of both Negro males and females with positive Kahn had positive lymphogranuloma fixation, only 18 and 21 per cent of the white males and females with syphilis gave this reaction. If syphilis were a frequent cause of false positive tests for lymphogranuloma, one would not expect this racial difference.

An investigation of the complement-fixation reaction in new-born Negro infants was carried out by testing 37 infants and their mothers. It was found that in every case the result in the infant was essentially the same as

that of its mother. In 23 of the 37 cases the test was negative in both, while in the remaining 14 the result was positive in both. Furthermore, in the positive cases the titers in infant and mother agreed closely. Follow-up tests were obtained from 2 to 4 months later on 9 of the 14 infants who had given a positive test at birth. These were all found to be negative at the time of the second examination.

After this investigation of new-borns had been completed, a similar study, done at Harlem Hospital, New York City, was published by Levine, Bullowa, and Scheinblum.⁵ Their findings were similar to ours.

L.V.C.F.=Lymphogranuloma venereum complement-fixation

DISCUSSION

There are two possibilities of error in the interpretation of the complement-fixation test for lymphogranuloma venereum. The first is that the test does not differentiate between antibodies for the agent of lymphogranuloma venereum and other viruses in the lymphogranuloma-psittacosis group.^{6, 7} However, so far as is known at present, none of the other members of this group causes infections in human beings in anything like the frequency found in the present study. Furthermore, none of the others is known to exhibit the special affinities for race and age group which were found in this work. A

second difficulty is the possibility that persons with other diseases may give false positive complement-fixation tests for lymphogranuloma venereum. Knott and his associates state that the specificity of the test is challenged by "the large number of positive reactions found in the sera of patients giving no history and presenting no clinical signs of the disease and also by the possible cross-reactivity with other venereal diseases, particularly syphilis."⁴ Their first objection is not very persuasive, since there is abundant evidence that many specific infections occur without inducing obvious disease. These workers do, however, cite some observations

on their own patients which indicate that a false positive complement-fixation reaction for lymphogranuloma venereum may occasionally occur in syphilitic individuals. On the other hand, Rake and his associates have furnished evidence that false positive complement-fixation tests for lymphogranuloma venereum due to syphilis are at least very rare.^{8, 9} The fact that immunological evidence of lymphogranuloma venereum is so common in individuals with venereal infections other than syphilis also appears to be significant. It would be surprising indeed if infection not only with the spirochete of syphilis, but also with the gonococcus and with the Ducrey bacillus were capable of giving rise to false positive serological evidence of this virus disease. We think it probable that the high incidence of positive tests for lymphogranuloma in individuals with syphilis and other venereal diseases is due to actual associated lymphogranuloma infection, even in the absence of clinical signs.

The findings in the present studies afford little evidence of congenital transmission of lymphogranuloma venereum. Although antibodies were found in the sera of some new-born Negro infants, they were probably the result of passive transfer from the mothers, since they had disappeared by the time the infants reached 4 months of age. The few positive tests which were obtained in older children may have been caused by acquired lymphogranuloma venereum infection or by infection with some other member of the lymphogranuloma-psittacosis group. Acquired lymphogranuloma venereum in children is not very rare; it may result from the use of contaminated enema tips, from close contact with infected adults, or from venereal practices.¹⁰

It is of interest that positive tests for lymphogranuloma venereum were found

almost as frequently in the older groups as in the age periods of greatest sexual activity. One might infer from this that the causative agent persists in the body throughout the life of the host, providing an ever-present antigenic stimulus.

SUMMARY

Complement-fixation tests for lymphogranuloma venereum were done on 879 hospital clinic patients, and the results were analyzed according to race, age, and sex. Approximately 40 per cent of adult Negroes and 12 per cent of adult white persons gave positive reactions. There were only 6 positive reactions among 116 Negro children under the age of 14 years, and only 1 positive reaction among 58 white children in the same age group. A sharp rise in incidence occurred after the age of 14 years. This is believed to be due to acquired venereal infection. The incidence of positive reactions was approximately the same in all age groups beyond the 4th decade. This persistence of an immune reaction in age groups where sexual contacts are less frequent suggests the possibility that the virus persists in the body, providing continued antigenic stimulus.

Comparisons were made of the complement-fixation reaction in new-born Negro infants and their mothers. It was found that immediately after birth the reaction in the infant's serum is the same as that of the mother. Nine infants who had given positive reactions were re-tested 2 to 4 months later; they had all become negative. It appears, therefore, that a positive test at birth is due merely to the passive transfer of antibodies from the mother.

The error introduced by the fact that infection with other members of the lymphogranuloma-psittacosis group of viruses will give rise to positive complement-fixation test for lymphogranuloma venereum cannot be assessed. It

is not likely, however, that the prevalence of infection by the other agents in this group is sufficiently great to distort markedly the picture of the prevalence of lymphogranuloma venereum.

A comparison was made of the results of the Kahn test and the results of the complement-fixation test for lymphogranuloma venereum. The incidence of positive Kahn reactions in the entire group was 32 per cent for adult Negroes and 9 per cent for adult white persons. The distribution of positive results according to age followed much the same pattern as had been the case with lymphogranuloma venereum. These similar findings appear to be compatible in view of the fact that both diseases are acquired by sexual contact. Reasons are given for the belief that false positive tests for lymphogranuloma venereum given by individuals with syphilis did not play an important part in producing the similarities.

New York State Caries-Fluorine Demonstration

The New York State Department of Health recently began the dental examinations of school children in Newburgh, N. Y., which, with the city of Kingston, N. Y., is collaborating in a long range demonstration to determine the practicability of mass protection against dental caries by adding fluorine to public drinking water supplies. Newburgh will be the study area and Kingston the control. Dental inspections of about 1,000 children aged 5 to 14 years will be made in each city. The pur-

pose is to obtain at the outset of the demonstration a dental caries index which will serve as a basis of comparison with the terminal figures at the end of 10 years, the length of time which must elapse before the full benefits of the water treatment are realized. Included in the study will be a pediatric investigation of a representative sample of the child population, including a general physical examination, urine analysis, and x-ray films of the long bones and centers of ossification.

Serological Types of Hemolytic Streptococci Isolated from Multiple Cases of Scarlet Fever in the Same Households

G. E. FOLEY, F.A.P.H.A., S. M. WHEELER, M.D.,* F.A.P.H.A.,
AND W. L. AYCOCK, M.D., F.A.P.H.A.

Department of Preventive Medicine and Epidemiology, Harvard Medical School and School of Public Health, Boston, Mass.

THE modern concept of the epidemiology of scarlet fever embraces both the case and the carrier as sources of the new case. The differentiation of hemolytic streptococci into serological types¹ led to the hope that the epidemiology of scarlet fever could be more clearly elucidated by relating the carrier to the case or the case to another case in a direct chain of epidemiologic circumstance. However, the finding that most of the serological types may be the cause of scarlet fever,² together with fluctuations in the prevalence of the various types in the same population groups with reference to time and space, have complicated, rather than clarified, the epidemiologic relationships involved. Although in clearly circumscribed outbreaks, one type is usually the predominant cause of disease,³ the movement of a particular type is followed with difficulty in any sizable community. Indeed, endemic scarlet fever does not appear to be a function of any single serological type of hemolytic streptococcus; but rather a fluctuation in the incidence of several toxigenic types found among carriers in the population. Since the

dissemination of the hemolytic streptococcus may be accomplished through individuals who present no recognizable symptoms, it is usually not possible to determine whether a given case represents the introduction of a new serological type; nor is it always possible to determine with certainty whether a given group of cases are related to one another in the epidemiologic sense.

The ideal situation for studying the relation between cases would be afforded by an outbreak of the disease following the single introduction of a single serological type of hemolytic streptococci into a previously uninfected community. Such an opportunity is rarely presented to the epidemiologist. Multiple cases in families present perhaps the nearest approach to a readily accessible grouping of epidemiologically related cases; except in those comparatively rare instances in which infection follows mass exposure to the same infectious agent through accidents of environmental hygiene.⁴

Chapin's classic studies⁵ of familial aggregation in measles, diphtheria, and scarlet fever clarified the basic laws governing the dissemination of these

* Now on active duty with the U. S. Navy, at the Department of Epidemiology, Naval Medical School, Naval Medical Center, Bethesda, Md.

NOTE: The opinions presented are those of the authors and do not necessarily reflect the policies of the Navy Department.

infectious agents. These agents, under conditions of exposure in a family, when introduced, tend to spread throughout the household. They cause high secondary attack rates among the susceptibles, and in the case of *Corynebacterium diphtheriae* and hemolytic streptococci, high carrier rates as well. Aycock and Eaton⁶ in a study of Chapin's data, observed that secondary cases of scarlet fever, like those of measles, occur in two groups—(1) common source with, and (2) truly secondary to the first case in the family. They observed that 10 per cent of all secondary cases of scarlet fever occur more than 24 days removed from the first case, as contrasted with measles, where not more than 1½ per cent of the secondary cases occur so far removed from the initial case. The range within which secondary cases of scarlet fever occur appears to be due both to the variation in the incubation period and to the length of the period of infectivity; or possibly to the chance occurrence of another case in the same family. It seemed that the serological classification of hemolytic streptococci isolated from multiple cases of scarlet fever in the same household might establish bacteriological proof of the epidemiological relationship of the secondary case to the initial case in a given household; and at the same time, provide readily obtainable data concerning the spread of a single serological type in a previously uninfected group of epidemiologically related susceptibles.

During a 26 month period, throat cultures on 824 of 1,048 scarlet fever admissions to a contagious disease hospital in a local community* were examined for hemolytic streptococci. Of these, 598 were positive for Lancefield

Group A hemolytic streptococci. These strains were classified as to serological type according to the slide agglutination method of Griffith.¹ (The totals include strains from a previously reported study.⁷) Thus, cultural and serological data are available on 57.1 per cent of all scarlet fever admissions during this period. Of the cases studied, 134 (22.4 per cent) occurred as multiple infections in 55 families. There were seven different serological types of hemolytic streptococci involved in these 55 households, and, as would be expected, the type isolated from multiple cases in a given household was the same in each instance. These data are summarized in Table 1.

INTERVAL BETWEEN CASES IN FAMILIES

common-source cases from other outbreaks,† a total of 213 cases in all. The broken lines in the lower graph represent an estimated division into common-source and secondary cases, assuming that the incubation period is

† From the data available for study, cases truly secondary to primary common-source cases could be established only on single secondary cases occurring in 57 families, hence the upper graph in Figure 1 shows only 57 intervals.

most frequently between 3 and 4 days. The protracted course of family outbreaks of streptococcus infection is emphasized by the relatively high percentage of secondary cases which occurred 20 or more days following the original case or cases of scarlet fever in the given families. The maximum intervals between the primary and secondary case in the same household,

however, do not necessarily indicate the maximum duration of the convalescent carrier state.

It is evident in these studies then, that the occurrence of secondary cases of scarlet fever after a prolonged interval was not due to the chance introduction of a new infection into the same household, but was more likely the result of a spread through the family following the introduction of a single serological type of hemolytic streptococci. Such spread is not limited to case to case transfer, but includes non-scarlet and subclinical infection as well as intermediate carriers within the family. As pointed out by Gordon²:

... infection with a streptococcus that produces erythrogenic toxin can lead to two kinds of clinical reaction. The result in a Dick negative subject—a host with antitoxic immunity—is a local infection, corresponding to sore throat or tonsillitis. A Dick positive subject, lacking antitoxic immunity, develops the complete syndrome of scarlet fever . . . Field studies . . . showed a well-marked frequency of coincident sore throat or upper respiratory infection among family contacts of patients with classic scarlet fever.

SUMMARY

Thus, family outbreaks in general, probably are single-source outbreaks caused by a single serological type of hemolytic streptococci, whereas on the other hand, scarlet fever in a sizable

community appears to be caused by multiple types—perhaps due to the introduction of a number of strains from different sources. It may perhaps be postulated that endemic scarlet fever is composed of numerous outbreaks occurring in basic units of population such as the family, the whole of which gives the varied type-pattern characteristic of the disease in its endemic form. In other words, the epidemiology of endemic scarlet fever is complicated by the unavoidable multiplicity of human contacts, but in those circumstances where the movement of a particular serological type of hemolytic streptococci can be followed, person to person spread can be demonstrated.

A Citrate Gold of Optimal and Reproducible Sensitivity for Use in the Colloidal Gold Reaction

Its Preparation and Control

CARL LANGE, M.D., AND ALBERT H. HARRIS, M.D.,
F.A.P.H.A.

*Division of Laboratories and Research, New York State Department
of Health, Albany, N. Y.*

VARIOUS technics for preparing sols for use in the colloidal gold reaction have been proposed in the literature as modifications of the original technic,¹ in which formol was employed for the reduction of the gold chloride. The preparation of this original gold sol seemed too difficult for the average clinical laboratory. It was easy to find numerous other reducing agents, which apparently eliminated the difficulties and obviated the occasional failures of the formol method. The fundamental factors governing the results of the gold reaction were, however, in the beginning, entirely unknown. On the basis of present knowledge, it seems quite evident that every modification is bound to yield results inferior to those of the original technic, if the following fundamental factors are neglected: (1) the pH of the milieu, which has an optimum value of 7.4; (2) sensitivity of the gold sol, adapted to this required pH of the milieu; (3) aging of the gold sol.

Most of the modifications represented a deterioration of technic erroneously ascribed to the original gold reaction, and led to considerable discredit of the test. The quantitative gold reaction,² on the other hand, has twofold ad-

vantages. First, it meets the fundamental requirements to which reference has been made even better than the original method. Second, it meets the demand for an easy technic; the method is even simpler to perform than the description of it would indicate.

THE REPLACEMENT OF FORMOL GOLD BY A CITRATE GOLD OF SIMILAR SENSITIVITY

The preparation of gold sols for the gold reaction through the use of sodium citrate in the reduction of gold chloride was introduced by Borowskaja.³ She employs the gold sol obtained with a citrate concentration of 1:2,000; for convenience, it may be referred to as "citrate gold 1:2,000." A peculiar advantage of the citrate reduction consists in the fact that no strict adjustment of the reduction pH is required, provided it is acid. It is to be noted that this reduction pH may be quite different from the optimal pH of the milieu in the test itself, which is fixed at pH 7.4. In the formol method, on the other hand, unless reduction occurs within a narrow range, slightly above pH 7.0, proper dispersion of the particles in the sol does not occur. The pH of citrate gold 1:2,000 is about 5.8-6.0, deter-

mined by the potentiometer, i.e., much lower than that of formol gold. This acid gold sol is orange-red in color and of high transparency, which indicates a very small particle size and therefore much lower sensitivity than formol gold. Aside from the changes induced by aging, the sensitivity of a gold sol depends, first, on the size of the particles, and second, on the pH of the milieu. In order to obtain correct curves in the gold reaction, the pH must be approximately 7.4²; an orange-red gold sol of small particle size exhibits an unsatisfactory sensitivity at this pH. On the other hand, if the sensitivity is raised, as it is done in Borowskaja's modification by using a pH much below 7.4, false paretic curves are bound to occur in conditions such as purulent meningitis. Therefore, citrate gold 1:2,000 is not satisfactory to replace formol gold.

Sodium citrate or tartrate as reducing agents exhibit additional advantages not considered by Borowskaja and which may be utilized without any interference from an unsatisfactory pH of the milieu. Stable gold sols of widely varying but definite particle size may be obtained by keeping the concentration of the acid gold chloride constant, at 1:10,000, while varying the citrate concentration from 1:1,000 to about 1:15,000. In such a series of sols, the color and particle size vary progressively; the sol with the smallest particle size is orange-red in color and has the highest transparency. Those of larger particle size are burgundy-red, violet, and finally blue. The size of the particles in blue gold sols is so large that the sol is unstable. When the pH of the milieu in the test is 7.4, citrate gold 1:10,000, quite different from citrate gold 1:2,000, has about the same sensitivity as formol gold. It is much softer and more acid than citrate gold 1:2,000; its pH lies around 4.8-5.0. To use the sol in the test, its acidity

must be neutralized, by employing strong buffers of pH 7.4 as diluent instead of saline.

PRESCRIPTION FOR THE PREPARATION OF REPRODUCIBLE CITRATE GOLD 1:10,000

For the preparation of citrate gold sols 1:10,000, relatively pure distilled water is used. The requirements of purity, however, are far less severe than in the formol method, since a single distillation is sufficient. In this laboratory, untreated spring water is rendered definitely alkaline and then treated with permanganate in sufficient amount so that some color remains after storage for 1 week in sunlight. Actually any source is satisfactory if the water, after a single distillation, yields satisfactory gold sols. The water is then distilled once in Pyrex stills of 5 liter capacity (Scientific Glass Apparatus Company, No. J-1333 Yoe distilling apparatus, interjoint, Pyrex glass). After generous steaming, a first run of about 500 ml. is discarded. The pure distilled water is collected in Pyrex Erlenmeyer flasks which are cleaned from time to time by steaming. All glassware is scrupulously cleaned and is used for no other purpose. The original source of the water is satisfactory if a single distillation yields a pure distilled water with which hardly any failures occur in the preparation of citrate gold 1:10,000. As a rule, the water is distilled one day before the preparation of the gold sol.

The acid gold chloride at present used in this laboratory is "Baker's purified." Gold chloride has an inconstant water content, with a resulting variability in the gold content. Nevertheless, in preparing the gold sol for use in a quantitative gold reaction, the complete contents of six vials may be satisfactorily dissolved in pure distilled water. Each vial contains 15 grains, equivalent to 0.97 grams. The gold chloride is dissolved in pure dis-

tilled water up to a volume of 400 ml., yielding a stock solution of almost 1.5 per cent. The solution is kept in a brown bottle with a glass stopper. For accurate quantitative work, and particularly for experimental work concerned with standardization, the use of gold chloride solutions of tested gold content is indicated. The simple permanganate titration⁴ may be used for this purpose, but from the practical standpoint the testing of the prepared sol turbidimetrically is simpler and equally satisfactory. For preparing the 1.5 per cent sodium citrate solution, the weighing out of 3.0 gm. of Baker's T. P. on a good torsion balance and dissolving in pure distilled water up to 200 ml. yield sufficiently accurate results. The solution must be freshly prepared, since it is readily contaminated with molds.

In boiling the citrate gold, the volume and the shape of the container are of significance. A 2 liter Florence flask, not a beaker, of Pyrex glass is reserved for this particular purpose; batches of 1,500 ml. are invariably prepared. The flask is heated on a heating shield over a very large burner. Since it is important to keep the evaporation as constant as possible, an occasional check on this factor is indicated, as well as on the time until boiling occurs; the use of a reflux cooler is unnecessary. Before the gold sol is boiled, the flask is cleaned by boiling pure distilled water in it for 10 minutes. After the flask has been rinsed, 1½ liters of pure distilled water are brought to a rolling boil.

The gold chloride is then added with a 10 ml. Ostwald pipette, the flask is vigorously twirled, and 10 ml. of 1.5 per cent citrate are added in the same way. The flask is again twirled and then returned to the flame. First, a blue color appears, which, after some time, sharply changes to red. Then the boiling is continued with lowered flame

for 3 minutes, at which time the preparation is complete.

The gold sol cannot be stored in ordinary glass, as recommended by Borowskaja, because the walls of cheap glassware may become lined with a precipitate of blue gold within 24 hours. Two liter Pyrex bottles with glass stoppers are satisfactory. The bottle is first rinsed with a small portion of the hot gold sol and after the rest is poured into it, it is cooled for ½ hour in a vat with cold tap water. The Florence flask is rinsed with pure distilled water before the next batch is boiled. During the cooling, the storage bottle is closed with a cotton plug covered with cheesecloth, subsequently replaced by the glass stopper, which may be covered with paraffin to prevent sticking. The storage bottles are cleaned by steaming. Aqua regia is used only to remove a visible precipitate of gold, followed by a most thorough rinsing and, finally, steaming. After the turbidity has been checked to determine that it is in the normal range, the batches of citrate gold are pooled. At present, the gold sol is kept in a refrigerator compartment at a temperature of from 9 to 14° C. The aging is more rapid at higher temperatures, while on the other hand, the gold sol coagulates when it freezes. In any laboratory in which a sufficient number of cerebrospinal fluid examinations are performed, interference by aging is best eliminated by preparing only a sufficient amount of citrate gold for 1 week's use. The extent of aging may be determined by the turbidimetric test; however, the citrate gold is so inexpensive and so easy to to prepare without failures that it is not worth while to run the risk of using older citrate golds.

THE TURBIDIMETRIC CONTROL OF THE
REPRODUCIBILITY AND AGING OF
CITRATE GOLD 1:10,000

The reproducibility of citrate gold

1:10,000 depends primarily on the relative purity of the distilled water used; the purity is easily and reliably checked by the turbidimetric testing of the gold sols prepared from it. In order to demonstrate the effect of impurities, three experimental batches of gold sol were prepared; the first with "pure distilled water" prepared according to the preceding prescriptions; the second with "ordinary distilled water" the use of which was recommended by Borowskaja as a valuable simplification embodied in her technic; the third with pure distilled water to which 0.2 mg. per cent copper was added in the form of copper sulfate. The three gold sols exhibited to the naked eye such a spectacular difference in color and transparency that there could be no doubt about the fact that there was great difference in the particle size; the second and third batches were easily recognizable failures. The fact was observed, with the help of adequate test fluids, that the sensitivity of freshly prepared citrate gold 1:10,000 runs exactly parallel to its turbidity; after prolonged aging this no longer holds true.

The turbidity is determined with the photoelectric colorimeter; the Klett-Summerson is used in this laboratory with red filter No. 66 and the ordinary macro tubes, the interchangeability of which must be checked; the zero point is set with distilled water. The turbidity of the above three batches was equivalent to 138, 64, and 35, respectively; the last named batch was pale red in color and of highest transparency. These three batches when employed in the gold reaction, of course, yielded entirely different results. The turbidity of satisfactory citrate gold 1:10,000 lies around 130; variations from 120 to 140, or even more, are of no demonstrable significance. The turbidity of gold sols begins to decrease even during the cooling of the freshly

prepared gold sol and continuously afterward; after 3 days, there is a progressive slowing in the rate of change. In order to maintain fairly uniform conditions, the turbidity of a batch is determined after about 24 hours in the refrigerator at from 9 to 14° C.

Failure to obtain uniform citrate gold sols is often due to contamination of the ordinary distilled water. When the distilled water absorbs even small traces of copper from the still, pipes, or fixtures, marked variation in the turbidity of citrate gold sols prepared with such water will result. The effect of contamination with copper is shown in the third batch. There are additional possibilities of contamination in ordinary distilled water; in large stills with a float by which a constant level in the steam generator is maintained, there is no opportunity for volatile contaminating substances to be removed that otherwise are eliminated by discarding the first run. The failures invariably occurring when ordinary distilled water was used were exclusively associated with a too low turbidity. There is no reason for endeavoring to use ordinary distilled water, especially since a single distillation in a good still suffices for the preparation of satisfactorily pure distilled water.

As previously stated, the gold content of the stock solution may vary because of the inconstancy of the commercial gold chloride, which does not lend itself to the accurate preparation of a standard solution. The reproducibility of citrate gold 1:10,000 depends mainly on the purity of the distilled water and the gold content of the stock solution. The citrate solution can be readily prepared with accuracy, and failures in the preparation of gold sol in this laboratory have never been attributable to the citrate solution. Satisfactory purity of the distilled water is demonstrated if a fairly con-

stant turbidity is obtained in the examination of different batches prepared with the same gold solution. If the standard turbidity of about 130 is not obtained when "tested pure" distilled water and a new stock solution of gold chloride are used, the conclusion must be that the gold content is inaccurate. Actually, the previously mentioned permanganate titration of the gold is superfluous, because the gold content may easily be regulated so that the standard turbidity of approximately 130 is secured.

Finally, the turbidimetric method provides the best means for following, in a quantitative manner, the aging of citrate gold 1:10,000. Heretofore, an exact study of aging was impossible, mainly because of the great irregularity in the rate of change of the sol after a certain period of time. Although many factors that play a rôle in aging may be unknown at present, the satisfactory character of the sol may without difficulty be determined, so that the final results of the gold reaction remain reproducible with the highest degree of accuracy required. In the quantitative gold reaction, the effect of aging is reliably eliminated by restricting the use of a batch of citrate gold 1:10,000 to only 1 week. Even during this short time, the turbidity decreases, as from 130 to 100, with a corresponding decrease in the sensitivity. A decrease within a limited range does not affect the final result, since in the quantitative gold reaction the changes are quantitatively compensated by the use of the gold color standard, while in qualitative technics such slight differences could hardly be detected.

After a prolonged period of aging, either a sediment or precipitate of gold forms on the glass walls, indicating deterioration of the batch, or, less frequently, the gold sol, while remaining clear for a long time, exhibits a progressively decreasing turbidity.

Citrate gold 1:10,000 may occasionally be used considerably longer than 1 week, namely, as long as the test fluid yields the same curve as with freshly prepared gold sols, and the turbidity is not markedly lower than 90. It is unnecessary and unwise, however, to risk difficulty by using a citrate gold sol 1:10,000 more than 1 week old, and the maintenance of a fixed schedule of use, at least in the quantitative technic, is advisable.

SUMMARY AND CONCLUSIONS

Gold sols for use in the colloidal gold reaction prepared by reduction with sodium citrate have several advantages over the neutral formol gold, which, although effective, is difficult to prepare and is subject to unsatisfactory modifications. Gold sols of widely varying particle size may be obtained by reduction with sodium citrate. Further advantages are that the range of pH for effective reduction is broader, and the distilled water need not be as pure as was required by the formol method.

Gold sols obtained with a concentration of sodium citrate of 1:10,000 have a similar sensitivity, at pH 7.4 of the milieu, to that of formol gold. This is about the optimal sensitivity; gold sols prepared with higher concentrations of citrate, which are of an orange-red color, are unsatisfactory for purposes of the gold reaction.

Citrate gold 1:10,000 is definitely acid. The simplest way to neutralize this acidity in order to maintain the obligatory pH of the milieu, around 7.4, consists in the use of strong buffers as diluent, instead of saline.

The simple determination of the turbidity of citrate gold 1:10,000 with the photoelectric colorimeter provides an accurate and objective control of its reproducibility. The progress of aging may be similarly checked. By this method of control, identical gold

sols can be employed in different laboratories.

An amazingly simple qualitative test can be performed using citrate gold 1:10,000 in combination with buffers. The widespread vitiation of the results of the gold reaction, demonstrated by the appearance of false paretic curves in purulent meningitis, is easily eliminated in this way. The real value of this combination of standardized gold sol and buffers, however, will be appreciated only if the results are recorded quantitatively with the easily prepared gold color standard. The technic of

this thoroughly controlled quantitative gold reaction actually offers less difficulty than the original qualitative technic or its many modifications suggested as technical modifications.

Army Seeks Sanitary Corps Officers

According to an announcement of the U. S. Army, Office of the Surgeon General, Sanitary Corps officers have been placed in the scarce category. The Preventive Medicine Service of the Surgeon General's office is seeking qualified men to become commissioned officers and has announced the minimum requirements for enlisted personnel for appointment as second lieutenants.

Applicants must have a bachelor's degree with an appropriate science major and a minimum of 2 years' experience in the particular field in which the applicant is qualified. In exceptional instances, bacteriologists, biochemists, serologists and parasitologists may be considered for a commission upon the completion of one year of Army laboratory experience.

Backflow Preventer Installations

IRVING REICHMAN

Inspector of Water Consumption, Department of Water Supply, Gas and Electricity, City of New York, N. Y.

THE definition of requirements for correct air gap and backflow preventer installation, as set forth in the new ASA standard,¹ has served to clarify some of the problems involved in this phase of water supply protection. Inspection of a large number of backflow preventer installations has disclosed certain difficulties, some of which result from departures from the provisions of the present standard. An analysis of such faulty installations indicates that in the majority of cases there was a lack of acquaintance with the principle and operation of these devices.

The purpose of the backflow preventer (also known as a vacuum breaker, siphon breaker, anti-siphon valve, etc.) is to prevent back-siphonage of polluted or spent water into the water supply system when negative pressure (vacuum) develops in the supply line. It does this by breaking the vacuum, that is, by admitting air when the water flow ceases or reverses, as occurs under negative pressure conditions. The disc, piston, float, flap, vane or other closing mechanism in the mechanical type backflow preventer should close the air port or inlet under positive water pressure and open it when this pressure is removed. In other words, when the water pressure drops to a point too low to keep the disc, etc., in the "closed" position, then the disc should drop of its own weight to the "open" position. However, if the outlet end of the backflow

preventer is under appreciable head, then instead of opening the air port when the flow is stopped or reversed, the disc, because of the back pressure, may remain in the "closed" position or partly open, with the result that polluted water may flow or be drawn back into the supply system. This will not occur with all backflow preventers, the possibility generally depending on the particular design. In order that there may be no head on the outlet end it is essential that the backflow preventer be set above the level of the highest fixture outlet under supply line pressure. It must, of course, also be set above the highest fixture inlet and the fixture flood-level rim; requirements generally specified in the manufacturer's installation instructions. Back pressure may be caused not only by static head but also by pump discharge head. Supply lines equipped with backflow preventers should not be connected to pump discharge lines.

Paragraph 66 of the ASA standard prescribes the following limitations regarding the installation of backflow preventers:

"The backflow preventer shall be installed between the control valve and the fixture so it will not be subjected to water pressure, except the back pressure incidental to water flowing to the fixture.

"Backflow preventers, as prescribed herein, shall never be installed on inlet side of control valve, as they should not be subjected to constant water supply pipe line pressure.

"Furthermore, all backflow preventers shall be correctly installed according to the instructions supplied by the manufacturers."

The first two of these requirements practically preclude the use of positive side (inlet or pressure side) backflow preventers. These particular preventers are designed for use under direct or constant supply line pressure, i.e., either without a control valve or on the positive or inlet side of a control valve, as the latter is defined in the standard. Although no specification or provision for such installations is contained in the present standard a large number of positive side backflow preventers have been and are being installed. Their use in New York City is at present authorized by the Board of Standards and Appeals, and their installation is accepted under plumbing code and water department regulations.

Because positive side backflow preventers have both the inlet and outlet threaded, and some will allow water to flow in either direction, there have been instances where the supply line was found connected to the outlet and the discharge line to the inlet. This mistake of setting the backflow preventer on a side or treating it like an ordinary elbow has been most common in the installation of the smaller sizes. It is essential that the preventer be installed upright, otherwise the closing mechanism will not be actuated by gravity.

A backflow preventer should be of ample size, at least that of the supply line to it, in order both that the air port area may be sufficient to afford full vacuum relief and to reduce pressure loss. Some backflow preventers cause an appreciable pressure loss and this reduction in water pressure may prove troublesome. Where the inlet pressure of an unprotected supply to a fixture, machine, apparatus, etc., is just sufficient for proper operation, the installation of a backflow preventer may result in an outlet or residual pressure lower than that required for satisfactory operation of the fixture, etc. This sometimes occurs with commercial and

industrial installations in low pressure distribution areas, and is also quite frequently true of flush-valve type backflow preventer installations where the inlet pressure at the fixture is poor or barely sufficient to start with, as is often the case on the upper floors of a building wholly supplied through an up-feed system. (A down-feed system, although subject to static pressure conditions similar to those of an up-feed system, is ordinarily not subject to backsiphonage.) Given sufficient volume, the effectiveness of siphonic action flushing of a water closet, for example, depends chiefly upon the pressure at the fixture inlet. Where this pressure is too low it often becomes necessary to flush five or six or more times before cleansing results. In this regard, inspectional tests have shown many flush valve-backflow preventer installations which were acceptable from the sanitary standpoint in that the possibility of contamination through backflow was eliminated, but which were unsatisfactory from the conservation standpoint in that water waste was either introduced or became worse. On sanitary inspections calling for backflow elimination the author makes pressure tests to guide him in writing the correction specifications. Where the static or the estimated residual pressure is found to be insufficient for proper operation of flush valves a frequent recommendation is the replacement of the flush valves by anti-siphon flush tanks. Other tests and recommendations for backflow prevention are also made and these vary according to the particular conditions or circumstances.

Outdoor backflow preventer installations should, wherever possible, be avoided. Aside from the danger of freezing, the greater objection is the possibility of dust getting into and clogging the air ports. This would make the backflow preventer ineffective;

therefore, unless unavoidable, these devices should not be installed outside or in inside locations where they would be subjected to heavy dusts, particularly those of an industrial nature. However, where this is unavoidable, as with some outdoor water supplied structures, playgrounds, etc., then some form of dust hood such as a simple, inverted (open bottom) cylindrical can, about 1½ feet long, should be fitted over the backflow preventer, and the entire assembly examined periodically.

The author has seen backflow preventers correctly installed on jobs under construction, only to come back a week or two later to find that the pipe coverers had covered and completely sealed in the preventers as they often do check valves and other fittings. Hence the advisability of a final inspection. In at least one instance a Venturi-type backflow preventer was disconnected and removed because "it was entirely too noisy." Spurting (spitting) and leaky preventers are a nuisance. An obstructed or improperly seated disc will cause a continuous leak through the air inlet. Tamper—in a few cases air inlets were found plugged—has resulted from attempts by the inexperienced to stop such leaks.

A backflow preventer installed on the positive or inlet side of a control valve or fixture in continuous service is constantly under supply line pressure and quite a few positive side preventers have been found in which the disc or operating part was immovably frozen in the "closed" position. Backflow preventers in this condition are obviously useless for preventing backflow. Although a proper air gap is the best protection against backflow, the use of a check valve as an additional safeguard with positive side backflow preventers merits some consideration.

Regarding check valves it is frequently asked, "Isn't the ordinary

check valve sufficient protection against backflow?" A good check valve in good working order and properly installed would, in general, prevent backflow. But check valves, unless they are examined regularly and often, are not to be relied on, especially after they have been in service some time. Checks which do not seat properly because of obstruction or defect are common. In a recent investigation of a water contamination hazard in a hospital comprising several units, the source of the trouble was traced to a defective swing check in one of the buildings. A check valve alone is not sufficient protection against backflow, but when installed on the outlet side of a backflow preventer the combination may be considered a more satisfactory, though not necessarily an absolute or permanent, protection.

Backflow preventers have been mistakenly used as pressure relief valves on water-cooled refrigerating unit installations.² Contrary to code, a number of spring-actuated vacuum breakers have been connected in water supply lines, but wherever found these are ordered removed. In New York City only those backflow preventers which are approved by the Board of Standards and Appeals are permitted, and thus far none but the gravity-actuated type of mechanical backflow preventer has been approved.

The steady improvement in backflow preventer design has helped to eliminate faults inherent in some of the earlier models. Other difficulties connected with the use of backflow preventers will also disappear as codes are clarified and coordinated and information on these devices is disseminated.

SELSKAR MICHAEL GUNN

THE death of Selskar Gunn on August 2 has deprived the cause of public health of one of its wisest and most imaginative leaders.

He was born in London, May 25, 1883, of partly Irish ancestry which helped to color his vivid temperament. After coming to this country, he became one of "Sedgwick's boys" taking his bachelor's degree at M.I.T. in 1905 and, later, his C.P.H. at the Harvard-Technology School for Health Officers in 1917. He began his career as a bacteriologist (as did so many public health pioneers of his generation); served as Health Officer of Orange, N. J., in 1908-1910; and taught under Sedgwick at M.I.T. from 1910 to 1919, rising to the rank of Associate Professor. He held a post on the staff of the Massachusetts State Department of Public Health from 1914 to 1916.

Selskar Gunn rendered invaluable service to the American Public Health Association during the formative years of its transformation from a small group of health officers to a strong continental professional society. He was Secretary from 1912 to 1918; Managing Editor of this JOURNAL from 1912 to 1914; and Editor from 1914 to 1918.

The first World War drew Gunn into the wider international fields of public health which were to command his major interest for more than twenty years. He served with the American Tuberculosis Commission in France (and as a Captain in the Red Cross) from 1917 to 1920; as Advisor to the Ministry of Health of Czechoslovakia from 1920 to 1922; and in the Paris office of the Rockefeller Foundation from 1922 to 1932. He was placed in charge of all the health work of this organization in the European area; and was made a Vice-President of the Foundation in 1927. His intimate knowledge of problems and personalities—with the prestige of the Foundation behind it—proved of incalculable value. The writer recalls one typical instance. The position of Stampar, the splendid health leader of Yugoslavia, was threatened by a political cabal. Gunn took the Orient Express and called on the King to say how pleased the Foundation was with the magnificent progress Yugoslavia was making under Stampar's guidance. That was all; but it was enough. Stampar's good work went on.

In 1937 Gunn was sent by the Foundation to China where he remained for

the better part of five years. The plan which he developed for a broad program of social welfare—in which the artificial boundaries between health and education and agriculture and economics were broken down—was perhaps the most significant achievement of his life. When the menace of Japanese imperialism is overthrown, this program will certainly be realized as a basis for the great emergent China of the future.

Since 1941 Gunn has been at home again, primarily engaged in the direction of a comprehensive study for the National Health Council of the functions of voluntary health agencies in the United States—a study which will shortly be completed by his associate, Philip S. Platt. In 1943, he served as the Secretary of the Committee appointed by Governor Lehman to organize the work of OFRRO, evolving plans which greatly facilitated the operations of its successor, UNRRA.

Selskar Gunn, among other honors, received decorations from the governments of Czechoslovakia, Denmark, France, Norway, Poland, and Yugoslavia. The fruits of his efforts in many parts of the world and the love of his friends meant more to him than any merely tangible rewards. His courage and loyalty, his wisdom and statesmanship, his driving conscience, his warm and eager and intensely human personality made him very dear to us. With him, we think always of the wife (Carroll McComas) whom he married in 1933 and who did so much during the past ten years to make his life happy and fruitful.

WHAT PRICE, THE SCHOOL HEALTH EXAMINATION?

THE routine machinery of the school health examination is now once more in active operation, throughout the country. It is one of the largest, and one of the most costly, enterprises in the field of community health. We may properly ask ourselves whether the machine in our home communities is geared to a reasonable maximum of efficiency, whether it is turning out the results which we have a right to demand. Justly or unjustly, the high incidence of various physical defects revealed by Selective Service examinations, will inevitably raise questions as to the success of past performances. Particularly at the present moment, the shortage of physicians for civilian service makes it imperative to use the time of precious professional personnel in the most efficient manner.

The underlying philosophy of the school health examination is sound. It envisages three procedures which are all eminently desirable:

A periodic medical examination of each child, sufficiently thorough to detect all important physical defects and deficiencies.

The actual use of this examination as a basis for the education of the child and its parents in regard to the application of the laws of health to that particular child; and for the adaptation of the school program, including physical environment, load of home work and physical exercise, to its individual needs.

The correction of those remediable defects which are discovered.

In some cities and even in some small rural communities this ideal is attained in reasonable degree. The family physician, the school physician, and the school nurse in such areas understand their job and coöperate effectively in its performance.

In other communities, the picture is a very different one. In a New York town the task of school inspection was, a few years ago, allotted in rotation to

three local doctors; one examined at a rate of 15 pupils per hour, another at the rate of 60 per hour. In another town the rate was 80 or 90 per hour. Perhaps a world's record was recorded in a recent survey of a Connecticut city—300 examinations made on each morning visit to a school. Where such a system prevails there can obviously be no real detection of defects, no education of the pupil, no hope of constructive service. As to the correction of defects discovered, it may be doubted whether more than a very few school systems have systems of medical bookkeeping of meaning and validity. Some have no records at all; some show 100 per cent correction year after year, with no reduction whatever in the number of defects found in the same children in successive years. The cost of school medical service in 18 New York communities varied from \$.17 to \$.17 per child, and the most efficient services were by no means always in the highest cost ranges.¹

The figures cited above are for extreme cases. Many schools have a health examination program which is sound and fruitful; but it is time that the laggards were brought up with the procession.

One important factor in promoting hasty and futile procedures is the existence of well-meaning but misguided state laws which require a routine physical examination to be made each year. No community is rich enough to provide a real examination on an annual basis; and if it were, such a procedure would be a needless waste of medical time. What we need is an examination (including heart and lungs) made in the presence of a parent and combined with specific instruction in personal hygiene which would require on the average at least 20 minutes. Examinations should be made before school entrance and, as a minimum, twice more during the period of school life and finally at the termination of school life; and always, of course, at any time on referral by nurse or teacher or after absence due to illness. A study made in Astoria, N. Y., showed that two to four times as many children with defects needing attention (other than those of dental and visual nature) were revealed by referral examinations as by routine examinations.

These physical examinations (either on referral or routine) need *not*, however, be all made by the school physician. Indeed every effort should be made to enlist the services of the family physician where family economic resources will permit. The chance of effective follow-up will be greatly enhanced in such families by this procedure. Full reports on standard forms should, however, be required for the school medical files.

Exactly the same principles should govern the treatment of defects. The family physician should provide such treatment (again reporting to the school service) if the family can pay the costs. If not, local clinic facilities should be utilized; and, only in so far as these are not available, the school medical service itself may be forced to step into the breach.

It is obvious, of course, that the medical examination is but one part of the total school health program, which must also include daily inspections and continuing classroom observation by the teacher, school nursing service, and home follow-up, coöperation of parents, availability of treatment facilities, and—above all—intimate integration into the total program of school health education and physical education.

Finally, if the school medical service is to operate successfully competent expert supervision is essential. Most school physicians are—and should be—part-time employees. Today, what they know about their task is—too often—that

the law calls for "an examination," and that they have the job of making "examinations" at so much a head. The payment on a capitation basis itself directly tends toward a high pupil-per-hour maximum. Part-time school physicians should be paid for their time, not on a capitation basis; and they should be supervised by a competent full-time local or county or state full-time school physician. The qualifications for such full-time school physicians have been outlined by the Committee on Professional Education² of the A.P.H.A.

The ideal set forth is not a Utopian dream. It is attained in certain favored areas; and it represents merely the adequate performance of our duty to the taxpayer who pays the cost and to the child who needs the services. The present service is in some communities the weakest link in the entire field of public health. Its improvement by the formulation of a definite program of reform is a clear challenge to our recently organized Section on School Health.

FROM HEALTH HONOR ROLL TO NATIONAL REPORTING AREA

ANNOUNCEMENT, in the May issue of the JOURNAL,¹ of awards to 53 communities in the National Health Honor Roll marks the 15th year of a program designed to stimulate improvement in local public health work. This competition has been fostered throughout by the U. S. Chamber of Commerce and the American Public Health Association and financed by the Metropolitan and other life insurance companies. In 1934 it was expanded to rural areas with the additional support of the W. K. Kellogg Foundation. The Canadian Public Health Association extended the scope to Canada with both English and French forms in 1937. Since the first announcement, 682 communities have submitted approximately 2,100 schedules and 201 different communities have received 615 awards of one kind or another.

The program of the A.P.H.A. in this field has passed through three successive phases. Originally, it was an outgrowth of the earlier experiences of the Committee on Administrative Practice which from its inception in 1920 had been interested in the construction of a simple method of expressing the mass of descriptive and factual material gathered in community health surveys. This interest culminated in the well known *Appraisal Form*, which was published in its first edition in 1925. The *Evaluation Schedule*, produced in its first form in 1929, was a modification of the *Appraisal Form*, reduced in size and with somewhat different emphases in aims and structure.

It was Chapin's epoch-making study of state health departments in 1914 that was mainly instrumental in directing attention to the practical advantages of expressing the extensive details of health surveys in terms of simplified numerical scores or grades which would be combined into a single total score. This proposal of expressing public health activity and achievements in terms of numerical scores precipitated heated debate in the early meetings of the Committee on Administrative Practice. Well do we recall how Chapin, Frost, Rankin, Freeman, and others argued back and forth for long hours over the desirability of

this innovation. On the one side was the fear of scientific unsoundness in attempting to place weighted values on the separate measures and practices followed in a public health program. Opposed to this was the feeling that the promotion of public health required some means of ready visualization of degrees of achievement in order to create understanding and interest on the part of both public and professional groups.

The surveys of the hundred largest cities of the country by the U. S. Public Health Service and of the 86 next largest cities by the American Child Health Association prior to 1925 brought to the front the practical necessity of adopting a numerical scoring method to portray in understandable fashion the extensive data there accumulated. It was such mass surveys of many communities rather than the isolated studies of single areas, many of which were carried on during the period from 1910 to 1930, that gave the main impetus to the introduction of the scoring principle in evaluation and appraisal of health work.

The periodically revised *Appraisal Form*, which grew from 40 pages in 1925 to 180 pages in 1938, provided two main features. It was a device for recording data in a uniform manner and it included numerical values and weights of items established by the group judgment of a committee made up for the most part of practising health officers. It was so arranged that the person filling out the form could, at the same time, compute the score attained. The primary purpose of the original form was to enable the health officer to evaluate the strength and the weakness of the various sectors in his battle area. In this respect, the development of an objective appraisal technic was, not only a basic contribution to the cause of public health, but a unique example of scientific self-evaluation of a public service.

In 1929, with the opening of the Health Conservation Contest—later the National Health Honor Roll—the work of the Association entered its second phase—that of inter-community competition. The *Evaluation Schedule* introduced for this purpose did not provide for self-scoring. The scoring was done by a central committee. Furthermore the new form contained several new principles: A poor score in certain important items branded an entire area of action as poor. Good scores in minor items were not permitted to compensate or out-balance poor scores in more important ones. Furthermore, where the *Appraisal Form* placed main emphasis on health department effort such as "number of visits" and "number of inspections," the *Evaluation Schedule* focused on the resulting health protection of the community as a whole, recognizing contributions in effort from all sources—private practitioners, voluntary agencies, and others—as well as from the health department.

Although the *Evaluation Schedule* is still far from a polished instrument, there is evidence of a basic advance in philosophy. It attempts to measure first, problems or needs; second, available resources, and third, as objectively as possible, the degree of success in applying appropriate resources to those various needs. Since the first step obviously is to identify the problems, there is a section on problem definition. Emphasis is placed on viewing the community as a whole. The quality, availability, and cost of medical services and facilities are important factors about which exact knowledge must be at hand if specific action is to be taken. The accent is on measurement of results rather than mere activity, i.e., the percentage of pasteurization plants that meet certain standards, rather than the number of inspections of such plants.

The new *Grading Chart* recently prepared for each participant is a significant

development. A panorama of the public health program is presented on a single sheet. Three columns, "good," "fair," and "poor," in which check marks are placed, have superimposed a system of colors, blue, green, and red. Blue colors the "good" column and some "fair" items, green the "fair" column but many "poor" items, and red the remaining "poor" squares. Column positions measure the items when considered alone. The color indicates the relative importance of the items in grading the section. Grading is accomplished by color, not by points. This system does away with numerical values of "false and delusive accuracy" and prevents compensation of glaring defects by other good programs. Further refinement is desirable but the method promises many interesting applications in evaluation technic.

A notable feature of the evaluation program has been the issuance with the aid of the Commonwealth Fund in 1943 of an intriguing booklet entitled "Health Practice Indices." This contains 60 charts depicting how 134 communities stand, relatively, in public health results, achievements, and activities. This "mirror of public health practices" as it has been aptly called, gives a community an opportunity to compare its own achievements with a sampling of practices over the country. This pictorial background of practice will figure prominently in the new program for the development of a permanent nation-wide reporting area.

The demonstrable contributions of the evaluation process to public health have already been worth many times the time and money invested. The *Evaluation Schedule* and its companion pieces, the *Grading Chart* and *The Indices*, are important today as never before. These tools can be, and frequently have been, used effectively:

1. By *local* health departments as an appraisal of the total community; as a basis for annual reports; as an outline for coöperative programs with related groups; as an index of budgetary needs for new services or equipment.
2. By *local* community groups such as Chambers of Commerce, labor organizations, industries, and others interested in developing more adequate services and facilities. It is particularly well adapted for analysis of war-expanded localities where community facilities such as housing, hospitals, etc., have belatedly been found to be as important as the size of the pay check and good working conditions inside the factory.
3. By *local* groups interested in developing sound post-war plans for new facilities of a community nature, either with local resources or with federal coöperation.
4. By *state* health departments in evaluating problems and programs in city, county, and district units on a comparable basis; in determining budget allocations, relative efficiency of personnel, or the need for supplementary services by the state health department; as a pattern for annual reports, etc.
5. By *national* agencies such as the Chamber of Commerce, labor unions, manufacturers' associations, hospitals, medical associations, U.S.P.H.S., A.P.H.A., etc., for representative cross-sections of the nation's problems and practices.
6. By the *A.P.H.A.* for the preparation of "indices" of current practice for the guidance of its officers, committees, and members, and as a basis for consultative services, program planning, etc., at local, state, and national levels.
7. By *universities* and schools of public health in teaching public health administration; in making useful studies of current practice as a service to local and state units; in developing the analytical sense of students in the true measurement of progress in problem solving and an understanding of truly balanced programs in the light of the needs of the people served.

This broad program for the development of progressively higher standards of public health service is now entering on its third phase. As indicated by its action in December, 1943, the Committee on Administrative Practice has decided to terminate the National Health Honor Roll and the granting of awards to high-

scoring communities. The annual submission of evaluation schedules will continue, but, in place of the awards feature, efforts will be centered on the development of a national reporting area for health practices.

The change from *contest* to *honor roll* a few years ago was in itself a real step forward. The competitive factor began to lose its usefulness as soon as the leaders in each class were definitely established. The honor roll substituted a standard of achievement which any community could attain with a good enough performance. This suggests still another evolution. A nation-wide reporting area (similar to the birth registration area) might be developed by having communities report regularly on a standard form based on the problem-solving philosophy of the present *Evaluation Schedule*. The value of the *Indices* alone would repay the communities for the effort entailed. Such a scheme might eventually prove of value to the U. S. Public Health Service as a means of obtaining a real picture of problems, resources, and accomplishments throughout the country. It certainly would represent a better measure of overall community health protection than reports of "number of services rendered" now customarily requested.

The experience with the Honor Roll in rural areas suggests a usefulness which has only been realized in a few states. In 1943 there were 48 returns from Michigan, 18 from Texas, 17 from Louisiana, 11 from Kansas, and 11 from Oklahoma. Where comparative data of this sort are available, the schedule can provide state directors of local health services with comparable local data based on problems and accomplishment rather than volume of work; and thus enable them to appraise the strong and the weak points in their local health services.

The development on a stabilized and permanent basis of a national reporting area for health practices is a logical and inevitable outcome of this well tried experience in health evaluation. In spite of occasional errors of judgment in the selection of outstanding communities, the fruits of this long pioneering effort have been eminently satisfactory. The practice of annual stocktaking is sound and necessary in reviewing the past and in planning for the future. The visualization of achievements and the opportunity to compare individual results with the general range of practice is a natural and strong stimulus to self-advancement. Such an undertaking merits the hearty support of federal, state, and local agencies in the attainment of its goal.

Not only the American Public Health Association but the cause of public health throughout the world owes a very real debt to the Metropolitan Life Insurance Company, to the W. K. Kellogg Foundation, to the Commonwealth Fund, and to the other agencies which have so generously supported the work of the Committee on Administrative Practice for a quarter-of-a-century. The significant program of Sanitary Indices prepared by the Health Section of the League of Nations was a modification of our American appraisal for international use. It is highly important that the latest and most important phase of our Association's work—the development of a National Reporting Area for Health Practice—shall be brought into full effect. Some way must be found to continue this work with whatever reorganization seems appropriate and with new sponsors if need be. The achievements of the A.P.H.A. in the self-evaluation and improvement of the practices of the public health profession are too vital not to be carried forward.

"THE PECKHAM EXPERIMENT, A STUDY IN THE LIVING STRUCTURE OF SOCIETY"

At the request of the Managing Editor, George Baehr, M.D., Director of Clinical Research, Mt. Sinai Hospital, New York City, has prepared a review of a most interesting report under the above title by Innes H. Pearse, M.C., and Lucy H. Crocker, B.Sc., recounting an adventure in health center work in London. Very few copies of the report have reached the United States, and Dr. Baehr has been asked to summarize the outstanding features, since he has retained an interest in the project for several years and has familiarized himself with its outworking. His review follows:

This is the third published report on the pioneer health center in London, which was established in 1926 under the leadership of Dr. G. Scott Williamson and Dr. Innes Pearse. The first preliminary report was published under the title, "The Case for Action." The second, which appeared a few years ago, shortly after occupancy of a new building in the Peckham area of London, is called, "Biologists in Search of Material." A fourth publication is promised in the near future.

This health center to provide preventive medical service to families was located in the Borough of Peckham, in South London, an area inhabited by people belonging to various economic levels, from the poor groups to the middle class, and representing various types of employment. The pioneer quarters which were established in 1926 were soon outgrown, and 7 years later a new building of steel and glass was erected which provided a club-like

atmosphere and at the same time served as a consultation center to which families living in the district rallied for social as well as health reasons. The new structure was in operation for about 4½ years when the war terminated its activities in 1939.

For the small weekly payment of a shilling by the family unit, the children were entitled to participate in all sport and recreational activities without charge; the adults paid small fees of sixpence or less only for certain of the recreational activities in which they joined.

The new building was adequate for 2,000 families. If this total membership had been reached, the family memberships and the small fees for the use of recreational activities by the adult members of the families would have defrayed the entire maintenance cost of the project. Almost 1,500 families had joined by the time the building had to be closed because of the war.

The health overhaul initiated the family's relationship to the Center. Once they had joined, the families were given complete freedom to use all the health and recreational facilities of the Center without much direction from the small nucleus of full-time members of the staff of the Center. The family health overhaul revealed that a surprising number of people required medical as well as social advice and guidance throughout the period of their membership. Members were classified from a health standpoint into three general groups. The first group included those who had actual disease—meaning *dis-ease* in the literal sense of the term—people who knew that they had physical disabilities and subjective

complaints. They were found to constitute, roughly, about 32 per cent of all members. Another 59 per cent were in a state of well-being—in other words, they had no *dis-ease*—but their physical examination disclosed disorders—some of them important disorders—of which they were entirely unconscious. Only 9 or 10 per cent were classified as absolutely healthy people in whom no physical disturbances could be found. As a result of membership in the Health Center over the years, these percentages were materially improved by correction of the disabilities and by improvement of living standards.

The significance of the Peckham Experiment is greater than that of any other form of preventive medicine which has thus far been attempted experimentally, because it was designed to guide families and helped them to guide one another in all medical, social, and environmental relationships which have an important bearing upon disease. New member families came under the influence of the member families who had been using this health service for some time. As a family increased in size, professional advice and guidance were available as preparation for pregnancy as well as during the prenatal and postpartum periods. Pre-marital consultations were available and were freely used. The children, themselves, brought problems of their own into the Health Center, for which they sought guidance. At the Center, they found quiet space in which to do their homework after school, as well as facilities of all kinds in which to indulge their physical activities. Above all, they found people at the Center who were able to guide and advise them in a sympathetic manner. The adolescents, with their special problems, also found the advice and help which they needed. Those who were of the age when courtship and mating are of special interest found this counsel particularly valu-

able. Even problems of social poverty were influenced by personal associations made between member families. The members developed an interest in one another. They influenced one another in their cultural development. Many developed a new breadth of vision in living. All these factors had an influence upon the diseases to which they were exposed.

A list of the welfare, educational, and health activities of the Center is impressive. It includes an antenatal clinic, postnatal clinic, birth control clinic, infant welfare clinic, care of the toddler, nursery school, immunization center, medical inspection of the school child, vocational guidance, sex instruction of adolescents, boys' and girls' clubs, sports clubs, and recreational clubs of all kinds. A country branch was established to which some of the family members could be sent during the summer, and to which members could be referred for convalescence after hospitalization or even after illnesses in the home. The building also provided keep-fit and gymnasium classes, adult cultural education, music, debates, drama classes and lectures of all kinds, citizens' advice bureau, holiday outings and expeditions, even a public billiard hall, and place for social gatherings.

Among the therapeutic activities were the marriage advice bureau, mothers' clinic, child guidance clinics, school care committee work, poor man's lawyer, hospital almony, which corresponds to our hospitals' social service, hospital follow-up, including all forms of after-care in their home or convalescent place for members discharged from medical care, and, finally, even a rehabilitation clinic. No actual medical therapy was practised, but members were brought into relationship with the proper agencies responsible for the technical part of rehabilitation or other services.

The Peckham Experiment has dem-

onstrated that families of a mixed economic group will gather together if proper facilities are provided, that they will get the idea of health through proper living, and will coöperate and stick to it over the years. Almost equally important is the demonstration that such a project can be self-supporting when adequate membership has been reached and the facilities of the institution are completely utilized. Although the project was a combination of a family club and a health service, the founders prefer to think of it as a biologists' laboratory designed for the prevention of disease through healthful living and for mutual aid in the amelioration of social poverty. Re-establishment of the enterprise is promised after the war.

PROMOTING HOME SAFETY IN NASSAU COUNTY, N. Y.

The Association's Committee on Administrative Practice has a Subcommittee on Accident Prevention which is paying special attention, under the Chairmanship of Donald B. Armstrong, M.D., 2nd Vice President, Metropolitan Life Insurance Company, New York, to the prevention of home and farm accidents. Through the work of this subcommittee, the following report is presented on Home Safety Activities of the Nassau County Health Department, N. Y.:

An effective home safety program is being conducted in Nassau County, Long Island, under the auspices of the Commissioner of the Health Department, Dr. Earle G. Brown. Nassau County, containing a number of medium urban communities and rural areas, affords an excellent proving ground for home accident prevention activities. A sectionalized view of the county shows that it consists of two cities, 63 incorporated villages, and 3 townships, with a population exceeding 450,000. The county has its full share

of public spirited individuals, many of whom are working on home safety through such organizations as the Red Cross, Nursing Council, Home and Farm Bureau, Child Care Committee, Boy and Girl Scouts, Parent Teacher Associations, and public utility companies.

It is apparent throughout the United States that home accidents are on the increase and Nassau County in the past year has proved no exception. With this in mind, as well as because of the war depleted availability of doctors and nurses, Dr. Brown instituted the Nassau County Home Safety Program which had its inception at the first Home Safety Conference last December. The program was carefully planned to stimulate the interest in home safety of the representatives of approximately fifty community organizations who attended the conference. From the reports of home safety work and the lively discussions conducted at intermittent intervals, it is not surprising that activities unfolded in a succession of stimulating events throughout the following months.

A number of organizations, young in the field of community life, such as the American Women's Voluntary Services and the American Women's Hospital Reserve Corps, at once made plans to incorporate home safety in their programs. Other organizations, such as the Nassau County Woman's Bar Association, gave generous space for a home safety exhibit at their first Woman's Annual Forum. Charts were displayed and literature dispensed at this Forum. The County Federation of Women's Clubs gave time on their program at their Annual Joint Meeting of all the Associated Clubs of Nassau County. An address was given by Dr. Brown, who urged continued action on the part of each member to carry on with home accident prevention work both individually and collectively. Sev-

eral organizations, such as the Police and Fire Departments, the Red Cross, and the Parent Teachers Association, have carried safety programs in their regular curricula for many years, and with an incentive born of Dr. Brown's planning, a new dynamic has been felt throughout all these safety activities. Naturally, these more seasoned organizations received great encouragement from the early winter's Home Safety Conference and with fresh wind in their sails increased both the volume and quality of their speaking, teaching, and poster contest programs, all of which will contribute, undoubtedly, to the decrease in accidents in the homes of Nassau County.

The nursing groups, in particular, show promise of developing into a vanguard of home safety work in the county. They are, of course, in an advantageous position to convey safe home practices wherever the nurses visit. The nurses are showing enthusiasm and diplomacy in their daily work, the technics of which they absorbed in their round table discussions on home safety.

A MINNESOTA INSTITUTE IN HEALTH EDUCATION FOR SCHOOL ADMINISTRATORS

Dr. George M. Wheatley, Secretary of the School Health Section, contributes the following review for Credit Lines:

It has been our good fortune to see a 78 page mimeographed publication from the Center for Continuation Study at the University of Minnesota, called "Health Education." It describes the Institute in Health Education for School Administrators, held at the Center for Continuation Study, January 6, 7, 8, 1944, under the direction of Ruth E. Grout, Associate Professor of Preventive Medicine and Public Health and Education at the University of Minnesota. It will be of interest

particularly to health educators and others who are planning workshop sessions on health education. The program for each of the three days is given. The Faculty are listed, and it includes such people as Donald A. Dukelow, Director of Public Health Education, Minnesota State Department of Health; Ruth B. Freeman, Associate Professor of Preventive Medicine and Public Health, the University of Minnesota; Orin B. Graff, Superintendent of Education, University of Tennessee; William A. O'Brien, Professor of Preventive Medicine and Public Health, and Director, Postgraduate Medical Education, University of Minnesota; Dean M. Schweickhard, Commissioner of Education, State of Minnesota; and Clair E. Turner of Cambridge, Mass., and the Office of Inter-American Affairs.

The approximately 75 registrants consisted mainly of superintendents of schools throughout the state, and directors of health and physical education. The talks given by the faculty members of the Institute are reproduced in this publication, and many of them are distinct contributions. For example, Dr. Dukelow's talk on "Making the Health Examination Effective," and the "Educational Aspects of the Health Examination," by Helen M. Starr, Associate Professor of Physical Education for Women at the University of Minnesota, ought to be read by everyone in school health work.

A symposium of special interest which is reproduced, is on the theme, "What Teachers Are Doing in Health Education." This series of talks by (a) an elementary teacher, (b) a physical education teacher, (c) a science teacher, (d) a home economics teacher, (e) a nurse, give those of us who are not familiar with the inside of a public school at the present time a stimulating picture of the potentialities in health education in the classroom. One of the best statements we have read on the

relationship of the school administrator to the school community program is Clair Turner's talk to the members of the Institute on the final day. The informality of his remarks lent color and effectiveness to the idea, and it is well worth writing to the University of Minnesota Press to get a copy of this publication simply to read Dr. Turner's statement. We are told that copies of this publication will sell for 75¢, and can be ordered from the University of Minnesota Press, Minneapolis, Minn.

TRAINING OF TEACHERS BY THE WORKSHOP METHOD

"I want to be identified with the School Health Section," wrote Jean V. Latimer, Coördinator of Health Education for the Massachusetts Department of Public Health, recently, "because the school health program is just now at a cross-road and there are many important things for us to do." She went on, "I think that the School Health Section could help to guide health officers in coming to see that whatever services health departments give to teachers should be in accord with progressive methods of education. Just recently I have seen some teacher training material which was sponsored by one of our more prominent state departments of public health in the West, which was developed on a didactic, old-fashioned type of teaching—a plan which we hope does not spread to other states. I am convinced from actual experience that our in-service training of teachers should be on a workshop basis, rather than on the formal lecture plan. Possibly we need to define and discuss with public health people what we mean by functional health teaching, both for teachers and for pupils. Certainly we need closer relationship between public health and the school administrative group."

Through an interesting coincidence, almost in the same mail came the sched-

ule of summer county workshop conferences for teachers in Kentucky arranged by Reba F. Harris, Associate Director of the Bureau of Public Health Education of the State Department of Health. Seven consultants from the State Department of Health were placed on schedule by Dr. P. E. Blackerby, Commissioner, to work with the workshops. Each was equipped to render a special type of consultant service on such things as communicable disease education, sanitation, tuberculosis prevention, malaria education, eye health problems, and vision and hearing testing. A glance at Miss Harris's outline with its generous use of motion pictures, field trips, demonstrations, chest x-raying of school teachers, and other things would indicate that the two weeks' workshop in each county was a lively affair. The whole plan is an example of the "functional health teaching" which Miss Latimer would employ with both pupils and teachers.

INDIANA WORKSHOP IN SCHOOL AND COMMUNITY HEALTH EDUCATION

The Indiana State Board of Health and Indiana University recently sponsored a Workshop for a period of two weeks at Bloomington under the direction of Willard Walter Patty, Professor of Education and Director of the Physical Welfare Training Department, and Frank S. Stafford, Director of the Division of Health and Physical Education of the State Board of Health and State Director of Physical Fitness for the Defense Council. Those interested in organizing similar Workshops will find it profitable to request outlines of the plans made for this Workshop by addressing Dr. Stafford at the State Department of Health, Indianapolis.

WE APOLOGIZE TO THE AMERICAN DENTAL ASSOCIATION

In August Credit Lines, there appeared an article entitled "How to

Find What Health Education Materials You're Looking For." Through a regrettable oversight the American Dental Association was not included in a list of national sources. Probably we figured subconsciously that everyone knew of the excellent dental health educational literature, movies, charts, posters, and exhibits produced and distributed by the A. D. A. Anyway, we are sorry. Next time we, and our guest editor, will keep our conscious minds on the job. For the record, the address is 222 East Superior St., Chicago 11, Ill., and the Director of the Bureau of Public Relations is Lon W. Morrey, D.D.S.

WORTH ACQUIRING

All the issues of the semi-monthly tabloid *Here's To Your Health*, published by the Fort Greene Industrial Health Committee, 295 Flatbush Ave. Ext., Brooklyn 1, N. Y. This committee is a unit of the Fort Greene District Health Committee of Neighborhood Health Development, Inc., and of the latter, Kenneth D. Widdemer is Secretary. *Here's To Your Health* is sub-titled "What You Don't Know Can Hurt You," and it is dedicated to telling industrial workers the simple, practical, elementary things they should know about nutrition, tuberculosis, venereal diseases, the health of mothers and babies, how to take care of a cold, how to avoid accidents on the job, and much more. It began publication on March 1, 1944, and each issue is better than the last. The September 1 issue is devoted to alcohol, although the writers would never say so. They would say it's about drinking, and their readers would understand them.

"Keeping Well," Volume 5 of the radio drama series as broadcast by the

Baltimore City Health Department and the Medical and Chirurgical Faculty of Maryland. These dramas deal with the common communicable diseases, including tuberculosis and syphilis, with industrial hygiene, occupational diseases, maternity and child hygiene, mental hygiene, food poisoning, the prevention of accidents, and the history of health broadcasting.

The *Bulletin* of the Research Council on Problems of Alcohol for March, 1944. It summarizes the development of this organization, a constituent society of the American Association for the Advancement of Science. It throws light on the newer developments for the control of alcoholism. Address the Council at 16 East 42nd St., New York.

"There Is Hope for the Alcoholic," Broadcast No. 17, available from the Welfare Council of New York City, 44 East 23rd St. It features Alcoholics Anonymous.

"How to Make a Speech and Enjoy It," by Helen Partridge, illustrated by Mary Stevens, and published by the National Publicity Council, 130 East 22nd, New York 10, N. Y. Price \$0.75. The pictures alone are worth the price of admission. The text contains many useful pointers not only for the inexperienced, but for those who are at ease on the platform, from long practice, but who always bore their audiences.

"Planned Health Film Production," by Adolf Nichtenhauser, M.D., Section of Medical and Health Films, American Film Center, 45 Rockefeller Center, New York, N. Y., reprinted from the *Journal of Health and Physical Education* for May, 1944. A discussion of the inadequacy of health films and the organization and financing of planned production.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted.

The Principles and Practice of Tropical Medicine—By L. Everard Napier, C.I.E., F.R.C.P. Calcutta: Thacker, Spink and Co., 1943, 522 pp.

This is the first and larger part of a textbook on tropical medicine by the Director and Professor of Tropical Medicine of the Calcutta School of Tropical Medicine who is now Visiting Professor of Tropical Medicine at Tulane University. He undertook the work because, at the time of preparation, there was no recent edition of a textbook in this field in the English language, and because of the demand for it by medical officers in India from Great Britain and the United States who required instruction to meet the demands in connection with the war.

The book is based upon the author's experience in India over a period of twenty years. It begins with a consideration of tropical environment and its relation to diseases, and measures to be taken by natives of temperate climates who take up residence in tropical countries. This is followed by a consideration of diseases due to the direct effects of tropical climate including heat stroke, heat exhaustion, heat cramp, the effects of ultra-violet sun rays, tropical anemia, etc. The bulk of the volume is devoted to malaria, leishmaniasis, trypanosomiasis, relapsing fever, rat bite fever, leptospirosis, the rickettsial diseases, Bartonellosis, yellow fever, Rift Valley fever, dengue and sand fly fevers, plague, tularemia, brucellosis, melioidosis, the intestinal fluxes, and leprosy.

With most of these diseases the author has had personal experience, and his presentations are excellent. He has de-

voted a large proportion of space to these diseases, and justifiably defends this in his preface by expressing the point of view that an author should give the detailed results of his own experience. The sections on malaria, leishmaniasis, plague, and the intestinal fluxes are particularly good from this point of view. A few of the diseases with which the author has not had personal experience, and which do not occur in India, are less completely presented, and perhaps less accurately. In the case of yellow fever, for instance, a map indicates that urban yellow fever is still endemic in parts of Central and South America from which it has been eliminated.

The work is presented primarily from the practitioner's point of view, and includes many important details of clinical diagnosis, but does not pretend to be a laboratory manual. Most of the illustrations, particularly maps, temperature charts, life cycles, and clinical photographs, are excellent. The colored plate illustrating intestinal parasites and arthropods, however, could be improved with considerable advantage. The author states that the completion of the work was prevented by his departure for the United States, but that much of the second part is in an advanced stage of preparation. This will include chapters on yaws, tropical ulcerative conditions, helminthic infections, dietary diseases, anemias, and snake bites. The index to the work has been postponed also, but the table of contents at the head of each chapter contains considerable detail.

The reviewer considers this an important contribution to the teaching and

reference literature on tropical diseases. It should be in the hands of all instructors in this field as well as libraries, military units of the armed forces, and many students of tropical disease. It is to be hoped that an American edition of the complete work with necessary revisions can be published in the near future so that it will be more easily available to American readers.

HENRY E. MELENEY

Industrial Ophthalmology—By *Hedwig S. Kuhn, M.D.* St. Louis: Mosby, 1944. 293 pp., 112 illus. Price, \$6.50.

This pioneer textbook has a unique place in that it appeals to two classes—the management group and industrial medicine—groups that in the past have been too widely divergent for the common good. It is to be hoped that these writings will correlate their efforts more closely.

The first three chapters are devoted to a very skillful presentation of the visual problems in industry, such as job analysis and the qualities of vision required for each job, technics for mass visual examinations, how visual defects among employees can be corrected, etc. These details are well illustrated, mainly by photographs, the majority of which are completely pertinent to the subject.

The fourth chapter comes from the expert pen of Dr. A. C. Snell and deals with industrial eye injuries. This is too technical for lay management to comprehend and a bit too elementary for the industrial ophthalmologist, but presents the matter clearly for the non-specialized industrial surgeon. Certain highly technical details of a specialized surgical nature could well have been omitted, but on the whole the chapter is well worth while.

Chapter V on Eye Protection is one of the most important parts of the book, emphasizing prevention of blindness from industrial accident. The

chapter is well written, well illustrated, and should be taken to heart by the management group as well as by the insurance group, interested in lowering the costs of compensation for eye accidents.

The final part of the book is given over to some of the newer aspects of industrial ophthalmology, flash-welding damage, shipyard conjunctivitis, etc. By and large, the book is very worth while and will bear close study by anyone even remotely connected with industrial ophthalmology.

HARRY S. GRADLE

Rose's Foundations of Nutrition—By *Mary Swartz Rose. Revised by Grace Macleod, Ph.D., and Clara Mae Taylor, Ph.D. (4th ed. rev.)* New York: Macmillan, 1944. 594 pp. Price, \$3.75.

So far as this reviewer is able to judge, this newly revised edition of Mary Swartz Rose's famous text is not greatly different from the previous one. The table of contents is essentially the same. Some slight rearrangement in the order of the treatment of topics is noted. The number of tables found in the appendix is greater, thus making the new edition more serviceable to many readers. One now finds tables dealing with such topics as market lists for moderate cost, low cost, and liberal meals, tips on buying and using food, vitamin equivalents, and the recommended dietary allowances of the National Research Council. The frontispiece of the former edition was a picture of Lavoisier; in the new edition one finds a good reproduction in color of a portrait of Dr. Rose, a fitting addition to the first revision of her book to be made by others after her death.

The format is slightly different, the new page being a bit larger. Certain sections of the former edition that were somewhat difficult to read now appear in larger type. Evidently this

matter of legibility was given careful attention because one finds also that many of the illustrations of the former edition are now printed in a manner much easier to read and appreciate. The larger page made it possible to keep the total compass of the book within 600 pages. One can offer further interesting evidence that the new edition was completely reset in type in the fact that on page 237 appears a passage identical with one in the previous edition except that in this paragraph this reviewer's name is now misspelled.

This 4th edition certainly maintains the high standard of excellence set by the previous editions, and is a volume worthy of a place on the shelf of everyone interested in the science of nutrition.

GEORGE R. COWGILL

The History of Miners' Diseases
—By George Rosen, M.D. New York: Schuman's, 1943, 490 pp., illus. Price, \$8.50.

This book presents a comprehensive research into a varied literature extending from Egyptian manuscripts to medical literature of the late 19th century.

The bibliography is voluminous and should be most valuable to students in industrial medicine and sociology. From a medical standpoint, the book covers a tremendous field in the long, and at times controversial, study of the pulmonary diseases of miners, and a criticism may be offered that there is frequent repetition, possibly due to the fact that the author's studies have covered the literature of France, Belgium, Scotland, and England. Much of interest in this book comes from its portrayal of the ages long social struggle of this important industrial group, as well as of other industrial workers.

Dr. Rosen has performed a monumental task and it is to be sincerely hoped that he will later present a second work covering the great developments of the 20th century from not only the

social and medical, but also from an engineering standpoint.

LLOYD NOLAND

Medical Care of the Discharged Hospital Patient—By Frode Jensen, M.D., H. G. Weiskotten, M.D., and Margaret A. Thomas, M.A. New York: Commonwealth Fund, 1944. 94 pp. Price, \$1.00.

This small volume is recommended as required reading for public health workers concerned with preventive medicine. It represents a one year experiment in extending extramural medical care to 902 patients discharged from the medical wards of the University Hospital in Syracuse, N. Y., of whom 165 patients were given home medical care by a full-time extramural resident. The experiment which was financed by the Josiah Macy Jr. Foundation was undertaken as a result of a teaching experiment introduced into the curriculum of the Syracuse University College of Medicine in 1930. Certain faculty members felt that medical education was laying too much stress upon disease rather than upon the patient suffering from disease. The responsibility was, therefore, placed upon each student of making a complete study of at least one patient, including a personal investigation of the home and the living and working conditions of the patient, and of the hereditary, environmental, social and economic factors which might play a significant part in the patient's illness or recovery.

The participants soon realized how unsatisfactory was the medical care available to most ward patients after discharge from the hospital. Approximately 85 per cent of the ward patients suffered from chronic diseases, and 90 per cent of the cost of hospitalization of patients on the general hospital wards was expended for such chronic illnesses. The extramural resident, who was also a member of the indoor medical

staff, knew all the patients before discharge, and as he was to take care of them in the home, the duration of many patients' stay in the hospital could be materially shortened. As was to be expected, many of the patients who received intelligent extramural medical care no longer found it necessary to return to the hospital repeatedly after discharge. When subsequent hospitalization was essential, they returned to the same hospital and remained for a much shorter period than patients hospitalized for the second time in another institution. One of the greatest savings was in the decreased need for re-hospitalization of patients with chronic cardiovascular diseases, who were responsible for approximately one-fifth of the total cost of hospitalization during the period of the experiment. The extramural resident took complete care of the 165 patients who had no physicians, but he also followed up patients discharged to the care of family physicians, the outpatient clinic and those who were transferred to other institutions. His influence in the homes of patients in disease prevention was perhaps the most important contribution of the experiment.

GEORGE BAEHR

Healthful Living for Nurses—By Harold S. Diehl, M.D., and Ruth E. Boynton, M.D. New York: McGraw-Hill, 1944. 534 pp. Price, \$2.50.

In *Healthful Living for Nurses*, the authors have presented not only a textbook but a reference handbook. Each of the 23 chapters is a brief text in itself presenting a wide range of topics of interest, beginning with "Safeguarding the Health of Nurses" and ending with "Community Health." One may be misled by the title "Healthful Living," for much of the book is given over to the discussion of disease. However, in each case preventive measures are suggested which if followed contribute to

healthful living, and Chapter X considers specific disease prevention.

In the first section of the book, the authors frequently refer to the nurse in the hospital and consider problems found in the institution. Keep on reading—for the nurse *not* in the institution will find the field broadens and principles that can well be carried over to the home, industry, or community organization are presented.

Each chapter presents the subject by a general overall review in digest form. No one school of thought is stressed but, with careful consideration, the East, West, North, and South—the scientist, philosopher, novelist, poet, and the authors contribute their thinking on the topic. The material is written in an interesting style.

After reading the book, you may wonder what the authors feel about certain controversial questions—the use of stimulants, the effect of smoking, or alcoholic beverages. The reader is allowed to consider various phases of the problem by the presentation of diverse points of view and by suggestions for other reference reading so that the answer to the question, "what will be my attitude toward . . . ?" is the reader's and not the authors'.

In addition, the student, the instructor, the group leader, will be grateful for the "Discussion Suggestions" and the "Reference and Reading Suggestions," found at the end of each chapter. Visual aids such as tables, charts, and diagrams are generously included all through the book as well as in greater detail in the appendices.

In the preface the authors modestly state that the subject matter has been brought up to date and made "applicable to the health problems and responsibilities of nurses." It might well be called the "What's What" in reference material for health orientation courses.

CAROLINE E. FALLS

Small Community Hospitals—*By Henry J. Southmayd and Geddes Smith. New York: Commonwealth Fund, 1944. 182 pp. Price, \$2.00.*

In a very readable manner this volume discusses hospital procedures and standards which are of direct interest to administrators, staff, board members and organizations working in coöperation with hospitals. While the material covered applies directly to the small community hospital, certain chapters of the book (particularly "Organization and Administration") are applicable to large institutions as well.

The rural hospital is discussed in terms of the experiences of a group of fourteen hospitals scattered from Maine to Utah which have been built under the Commonwealth Fund program. The book, written in non-technical language, takes up the contributions of the board of directors, the medical staff, and the superintendent and her staff. Each chapter attempts to treat the subject in hand from an objective point of view, dealing impartially with both professional and lay personnel. While it stresses the functional side, a chapter on building design, illustrated with diagrammatic plans, has been included.

In addition to the seven chapters, an Appendix has been included, listing, in addition to much valuable information, the fourteen hospitals built under the Commonwealth Fund program.

Any criticism which may be offered of the book would be only favorable. The volume is small, but contains a wealth of material. There is need for just such a book. J. ROY HEGE

The Problem of Changing Food Habits—*Report of the Committee on Food Habits. Bulletin 108. Washington: National Research Council, 1943. 177 pp. Free to Professionals and Agencies.*

The Committee on Food Habits,

largely made up of scientists from the fields of psychology, anthropology, and sociology, assumed the responsibility for this report "upon the methods of controlling the cultural forces which cause food habits to change."

In the preface, M. L. Wilson, Chief, Nutrition and Food Conservation Branch, War Food Administration, Office of Distribution, congratulates Dr. Carl E. Guthe, Chairman, and Dr. Margaret Mead, Executive Secretary, for the work of their committee. He says that "a new science of food habits is developing. This will be a handmaid to, and of equal importance with, the biochemical science of nutrition in efforts for the prevention of disease and facilitating man's progress toward optimum health."

The content covers a large amount of subject matter and is divided into four parts. The introductory chapters on the history of the committee by the Chairman, and the problem of changing food habits by the Executive Secretary are included in Part I. In Part II are reports on "Demonstration and Research conducted under Committee auspices." In Part III "Related Research" is reported, and in Part IV "Summaries of Committee conferences" are recorded.

A bewildering aggregate of information has been made available to the reader. It might perhaps have been arranged in a more logical fashion.

GERTRUDE GATES MUDGE

The War and Mental Health in England—*By James M. Mackintosh, M.D. New York: The Commonwealth Fund, 1944. 91 pp. Price, \$.85.*

This little book of essays is presented in very scholarly fashion by one of England's most distinguished authorities in the field of public health. Dr. Mackintosh has long been identified with the mental hygiene movement.

The first part deals with the impact

of war and carries the reader through the processes of adjustment on the part of the English people during the years 1939 and 1940. The fortitude evidenced by the entire population during the lonely years of 1940 and 1941 develops in the reader nothing but admiration for the way the English people have met adversity and prepared for the defense of their liberties.

Part two, "Mobilization for Peace," deals with post-war planning. Two statements present a challenge. "An interesting and hopeful development which has arisen indirectly out of the emergency hospital service is a growing emphasis on the mental health aspect of general hospital treatment." This is undoubtedly one of the greatest defects in the general hospital program in this country. The author in presenting some problems of the future has this to say about education: "Education must be the central feature of a post-war program for mental health. It is only through systematic health education beginning with the expectant mother and carried on with unflinching continuity from infancy to adolescence in the child that one can hope to create a generation of healthy people. . . . Even preventive medicine spends its effort upon the intermediate stages of disease. Child guidance, for example, is frequently concerned with behavior problems of children which could have been prevented by education; and the school medical and dental services spend far too much of their time in repairing faults that should not have occurred." MILTON E. KIRKPATRICK

Inadequate Diets and Nutritional Deficiencies in the United States—*Report of the Committee on Diagnosis and Pathology of Nutritional Deficiencies. Bulletin 109. Washington: National Research Council, 1943. 56 pp. Price, \$.50.*

All workers in the field of nutrition

and public health should be grateful for this Report of the Committee on Diagnosis and Pathology of Nutritional Deficiencies, of the Food and Nutrition Board, H. D. Kruse, M.D., Chairman. The committee has brought together the results of a number of dietary surveys and nutritional appraisals during the past 10 years. As stated in the preface of the report, it has been done both for convenient reference and to secure a more proper perspective of the nutritional deficiency problem in the United States. The committee has included also for the first time a considerable amount of dietary survey data previously unpublished.

It will be obvious to the reader, as indicated by the committee, that the surveys show that there is a widespread prevalence of moderately deficient diets and that in addition many factors beside food affect nutritional states. From data secured by new methods, it is indicated that "deficiency states are rife throughout the nation." It is pointed out that this presents both preventive and corrective problems; that effective production and distribution of food must be maintained; that further enrichment of appropriate foods should be considered; and that nutrition education should be extended and intensified.

It is of special interest to the medical profession to read the following concluding comments as to corrective measures: "There is need for detection and therapeutic treatment of deficiency states among the population. For this project it is necessary to disseminate the new diagnostic methods among the medical and public health professions. Foremost among the steps in this direction would be: (1) preparation of a handbook on methods of detecting deficiency states; (2) establishment of training centers for instruction in the medical aspects of nutrition, especially diagnosis of the deficiency

states; and (3) introduction of adequate courses on nutrition, particularly its clinical aspects, into medical schools."

An excellent bibliography of references is included in the report.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Correction Please—There is much more in this illuminating statistical study, but here is one observation culled from it that you may want to remember: when the age distribution for 1943 is adjusted (to account for the young men no longer in this country) the apparent increase in the crude death rate from 10.65 in 1940 to 10.87 in 1943 is more than accounted for; the corrected rate shows a decrease of 3.1 per cent instead of the indicated increase of 2.1 per cent.

ANON. Morbidity and Mortality from Specific Causes During 1943 and Recent Preceding Years. *Pub. Health Rep.* 59, 32:1047 (Aug. 11), 1944.

Vimms, Stamms, Bax, *et al.*—Are you one of the horde of vitamin takers? If so, you will be interested in this comparative table which tells you what you are getting and how much you pay for it. You pay through the nose, no matter what brand you favor.

ANON. Comparative Cost of Vitamin Mixtures. *J.A.M.A.* 126, 1:29 (Sept. 2), 1944.

Down on the Farm—Sanitary engineers have been listing the needed municipal water and sewage treatment projects, the provision of which would go far toward relieving post-war unemployment. To these urban sanitary needs may be added the rural deficiencies. It seems that there are 5 million country homes that cry for safe water supplies, and that an equal number of sanitary privies are still to be built.

ATKINS, C. H. National Inventory of Needs for Sanitation Facilities. *Pub. Health Rep.* 59, 30:969 (July 28), 1944.

About One Thomas Parran—For your clipping file, you may want this "popular" article on the U.S.P.H.S. and its Surgeon General, and you may be a bit surprised to find this eulogistic account in a publication which is not given to being overly sympathetic with bureaucrats.

COREY, H. *Guardian at the Gates of Health.* *Nation's Business.* 32, 9:36 (Sept.), 1944.

Too Much Bed Rest—When I annotated the item "Bed Rest May Be Lethal" in the June Bibliography, I supposed in my innocence that I was calling attention to the arresting and novel opinion of one intrepid breaker-of-new-ground. Only three months later appears this important symposium which particularizes upon the same idea. These authorities believe that extended rest may militate against improvement in heart disease, after surgery, and for certain neuropsychiatric conditions. And the writers lay no claim to originality in expounding their theses.

HARRISON, T. R. Abuse of Rest as a Therapeutic Measure for Patients with Cardiovascular Disease (and five related papers). *J.A.M.A.* 125, 16:1075 (Aug. 10), 1944.

Laboratory Intelligence—Experiments with yellow fever cultures lend further confirmation to the assumption that none of the viruses, so far studied, is susceptible to the action of the sulfonamides.

KOPROWSKI, H., and LENNETTE, E. H. Propagation of Yellow Fever Virus in Tissue Cultures Containing Sulfonamides. *Am. J. Hyg.* 40, 1:1 (July), 1944.

At a Cost of \$2.13 per—With the highest, large city syphilis rate among its military selectees, Philadelphia had a big follow-up job to do. The city Health Department had not the requisite staff, so a coöperative project was organized. Each registrant was sent a friendly letter advising him to seek treatment. This did the trick in 2 out of 5 cases. Two weeks later the others received a tough letter which produced results in almost another 1 out of 5. How the 2 remaining recalcitrants were brought to heel is the burden of this paper.

KRESGE, A. M. A Technic of Follow-Up of Selective Service Registrants With Syphilis in Philadelphia. *Ven. Dis. Inform.* 25, 6:167 (June), 1944.

We Need More Papers of This Kind—So practical and down-to-earth is the advice to the public health nurse about problems she will have to solve in attempting to carry an increased tuberculosis case load that this paper becomes of interest to more of us than the nurses to whom it is directed.

LINCOLN, L. A. Solving Tuberculosis Problems in War Time. *Pub. Health Nurs.* 36, 8:394 (Aug.), 1944.

Extended Medical and Hospital Service for Industry—This symposium is mostly about the Wagner bill and what industry, industrial medical services, and insurance companies can do to forestall governmental health insurance plans.

MANSON, M. H. What Is Extended Medical Service? (and five related papers). *Indust. Med.* 13, 8:609 (Aug.), 1944.

Foot Note for the Future—DDT, the valuable, new and as yet unavailable insecticide, was fed in large doses to a variety of farm and experimental animals. The lesions that were produced are described—the most outstanding being tremors in the muscles of extremities.

NELSON, A. A., *et al.* Histopathological Changes Following Administration of DDT to Several Species of Animals. *Pub. Health Rep.* 59, 31:1009 (Aug. 4), 1944.

Penicillin Gallops to the Rescue—Briefly outlined is the present-day status of the treatment of both syphilis and gonorrhea. If you read extensively in this field, you will find little that is new to you here, but still the condensed summary should prove illuminating.

NELSON, N. A. The Treatment of Syphilis and Gonorrhea as of Today. *Am. J. Nurs.* 44, 8:737 (Aug.), 1944.

Skin vs. Deep Cancers—This man believes that many inoperable cancers might be prevented by provoking and removing skin epitheliomas. Once more he asks that a commission of experts be appointed to consider his suggestion.

PELLER, S. Race, Stock and Environment in Human Cancer. *J. Hered.* 35, 6:175 (June), 1944.

Did Deficient Italian Health Service Play a Part in That Country's Downfall?—Though this paper is mostly about the exotic diseases the soldiers will bring home with them, there is much searching consideration given to the effect of the military experience of both medical officers and enlisted men upon the future of medical care and public health. Addressed to a Massachusetts audience, it still has wide applicability.

RUSSELL, F. F. The War and Public Health. *New Eng. J. Med.* 231, 7:225 (Aug. 17), 1944.

Last Word on Post-Vaccinal Jaundice—Considered most plausible is the hypothesis that the agent causing the lamented outbreak of jaundice in 1942, following yellow fever vaccinations, was the accidental introduction of a virus capable of producing jaundice when supposedly normal human blood was used in the manufacture of the yellow fever vaccine. Serum-free vac-

cine is now practical, so there need be no recurrence of the disease among our troops.

SAWYER, W. A., *et al.* Jaundice in Army Personnel in the Western Region of the United States and Its Relation to Vaccination against Yellow Fever. *Am. J. Hyg.* 40, 1:35 (July), 1944.

Showing Us the Door—It is now plain to all that industrial health is not a social project, nor even a public health project: it is an enterprise of industry and medicine, says the editor in the issue of *Industrial Medicine* that carries a fine symposium on the employment of the sub-standard worker. Any public hygienist who refuses to have the door editorially slammed in his face will find the papers useful. Heart cases, neuropsychiatric workers, the maimed, and those with defective eyes and ears are the objects of consideration.

SHAFER, M. M., *et al.* Who Can Work? *Indust. Med.* 13, 7:531 (July), 1944.

Insured Medical Care—If you hate the Wagner-Murray-Dingell Bill and all its social implications, then you will dislike this dissertation on health insurance. If the door of your mind is the least bit ajar, you cannot but be impressed with the reasonableness of

this persuasive writer. If the bill is defeated, as it is likely to be, for our present Congress is conservative he says, then we may expect another similar bill because the need remains as acute as ever.

SIGERIST, H. E. Medical Care for All the People. *Canad. Pub. Health J.* 35, 7:253 (July), 1944.

Department of Inner Meaning of Words—Preventive medicine, these writers assert, is commonly restricted to mean the intervention in a limited range of situations in which a specific disease can be warded off or a specific deterioration can be forestalled. The logical culmination of preventive medicine transcends the healing of the sick and becomes the building and maintenance of health. Ways in which the training for these broader goals can be integrated in medical education is the point of this paper.

In the succeeding issue of *Science*, Iago Galdston points to the connotations which unfit the term "preventive medicine" for serving as the name of this new endeavor, and he bravely proposes as a substitute, "eubiotic medicine." Have you a handier handle?

SMITH, G., and EVANS, L. J. Preventive Medicine. An Attempt at a Definition. *Science.* 100, 2586:39 (July 21), 1944.

NEWS FROM THE FIELD

FORECAST OF POST-WAR NEEDS IN SANITATION FACILITIES

According to an announcement by the Division of Sanitary Engineering, U. S. Public Health Service, Washington, there are deficiencies in water supplies, sewage disposal, and other sanitary facilities in many urban and rural areas throughout the United States, which now menace the health of millions and cause huge economic losses. Four studies have recently been completed as parts of a national inventory of needs for sanitation facilities. Needs are presented which include an estimated total of three and a half billion dollars which should be made available as quickly as supplies of labor and materials and other practical considerations permit. These would largely pay for themselves in savings of health and economic losses according to the Public Health Service engineers.

The inventory of rural sanitation needs shows that more than five million rural homes now need new or improved water supplies and that more than five million rural homes—including 846,148 entirely without toilet facilities—need sanitary privies as a minimum. This inventory shows that an estimated 50,000,000 persons or 12,000,000 families, are not now served by public water supplies and that a total of approximately 6,550,000 rural homes are not supplied with running water. The estimate would require about \$265,000,000 to provide safe water supplies for the 5,294,000 rural homes which need them. It is further estimated that it would cost about \$180,000,000 to provide privies for the new homes now without sanitary facilities and to replace half of the 8,505,572 existing outside toilets, about 50 per cent of which are insanitary.

The inventory of public water supply

facilities indicates that new and extended water supply systems costing more than \$800,000,000 are needed to serve adequately the 86,000,000 persons who now are served or could be served by public water supply facilities in communities with 200 or more population. Estimates of loss from sanitary and other defects in public water supplies include \$24,000,000 from water of excessive hardness, \$10,000,000 from water-borne disease, and at least \$10,000,000 because of miscellaneous other defects in the quality.

The inventory of public sewage needs in states indicates that there is need for \$2,255,000,000 in new or additional sewers and sewage treatment systems for almost 14,000 of the 16,752 communities in the United States. This includes an estimated cost of about \$1,200,000,000 for needed new sewer systems and extensions and \$1,000,000,000 for facilities to treat sewage and industrial wastes. The Public Health Service engineers estimate that the annual cost of water pollution which would be saved by such investments, would over a period of years very nearly pay for all the sewage treatment needs of every community of more than 200 inhabitants in the United States.

A final study on milk pasteurization needs proposes 438 milk pasteurization plants which would cost an estimated \$8,123,500 for 34 states and Alaska. The yearly economic loss attributable to milk-borne disease outbreaks in the United States is at least \$3,000,000, mostly due to raw milk. The inventory showed that more than 97 per cent of milk supplies of communities in cities of 500,000 population or more is pasteurized but that less than 25 per cent is pasteurized in communities under 2,500 population.

PLANS FOR STATE HEALTH DEPARTMENT BUILDINGS

Commissioner J. E. Offner of the West Virginia Department of Health is anxious to obtain information concerning plans, specifications, and costs of any building erected within the past five years for the sole use of a state health department.

Similar plans concerning health department buildings proposed for post-war construction would also be helpful in formulating a post-war building program for the West Virginia State Health Department.

If readers can supply any information along these lines, they should communicate directly with Dr. J. E. Offner, State Health Department, Charleston 5, W. Va.

MICHIGAN SCHOOL OF PUBLIC HEALTH APPOINTMENTS

Henry F. Vaughan, Dr.P.H., Dean of the School of Public Health, University of Michigan, Ann Arbor, has announced that Earnest Boyce, M.S., has been appointed Professor of Municipal and Sanitary Engineering in the College of Engineering and Professor of Public Health Engineering in the School of Public Health. Mr. Boyce for many years was Chief Engineer of the Kansas State Board of Health and served as Associate Professor of Sanitary Engineering at the University of Kansas. He has recently been on duty with the Public Health Service as senior public health engineer.

Dr. Vaughan also announced the appointment of John J. Hanlon, M.D., M.P.H., as Resident Lecturer in Public Health Economics, to be associated with Nathan Sinai, Dr.P.H., in that field. Dr. Hanlon received his training at Massachusetts Institute of Technology, his M.D. from Wayne University, and his M.P.H. in 1942 from Johns Hopkins University. For 6 years he was associated with the Detroit De-

partment of Health and then became Health Officer in Bradley County, Tenn., later Director of Nutrition for the Tennessee State Department of Health and Acting Associate Professor of Public Health Administration at the University of North Carolina School of Public Health, Chapel Hill.

The appointment was also announced of Robert Smalley Ingols, Ph.D., as Instructor in Public Health Engineering. Dr. Ingols has been Research Fellow for the Florida Citrus Commission at Winter Haven. He received his Master's degree at Columbia in 1937 and his Ph.D. from Rutgers in 1939. He later served as chemist and research fellow on several water and sewage projects in New Jersey and New York City.

CHILD GUIDANCE CLINIC IN BROWN COUNTY; WIS.

Brown County, Wis., by action of its Board of Supervisors, will employ a psychiatrist to hold a child guidance clinic for the furtherance of mental hygiene. This continues a demonstration program carried on for two years by the Wisconsin State Board of Health. Brown County is said to be the first county in Wisconsin to take steps to inaugurate a mental hygiene program. On the committee are G. M. Shinnors, M.D., Health Commissioner, Green Bay, and M. W. Meyer, M.D., District State Health Officer.

MISSISSIPPI STATE BOARD COMMENDED FOR CARE OF PUBLIC HEALTH

The Jefferson Davis County Committee of One Hundred, composed of civic minded Negro citizens of the county, recently paid tribute to the Mississippi State Board of Health and its Director, Felix J. Underwood, M.D., Jackson, for the effective health program carried on for the benefit of all people. According to the *Journal of the American Medical Association*, the

letter acknowledging the tribute was sent to Dr. Underwood because the committee "was especially proud of the local staff whose members are thoroughbreds without exception, competent, efficient, devoted to duty and possessed with a keen appreciation of human personality." According to the letter this agency "is an endorsement of the American way of life and points the way for future action." The Committee of One Hundred is an organization for the general improvement of the conditions of the colored people in Mississippi.

AMERICAN RED CROSS REPLACES NURSING CHIEF

The American Red Cross has announced that Miss Mary Beard, who for the last 6 years has been Director of the American Red Cross Nursing Service, has resigned for reasons of health. Virginia M. Dunbar, who has served as Miss Beard's deputy, will be her successor.

Appreciating the work which Miss Beard has done in war and peace, the Red Cross pointed out her responsibility for the recruitment of 50,000 American nurses who have been added to the Army and Navy Nurse Corps and her work on many of the wartime committees developing the Nurses' Aide Corps and other services. Miss Beard was formerly on the staff of the International Health Division, Rockefeller Foundation.

Miss Dunbar, former Assistant Director of the University of California School of Nursing, San Francisco, has been on the staff of the Red Cross for 6 years and has been identified in planning the home nursing courses now being given throughout the country.

NUTRITION FOUNDATION AIDS RESEARCH

According to the report of Charles Glenn King, Ph.D., Scientific Director of the Nutrition Foundation, Inc., New

York, N. Y., the Foundation has appropriated since May, 1942, when its first grants were made, more than \$530,000 for studies in the science of nutrition. Studies on the human requirements of specific nutrients received \$66,000, studies on the origins and functions of individual nutrients received \$134,000, maternal and infant nutrition \$26,000, public health problems in nutrition \$106,000, educational and professional training \$42,000, and nutrition studies related directly to the war \$151,000.

METROPOLITAN LIFE PROMOTES PUBLIC HEALTH LEADERS

Among those recently listed for promotions by the Metropolitan Life Insurance Company, New York, were the following, with the new titles:

Donald B. Armstrong, M.D., New York.
Second Vice President in charge of welfare.
Louis I. Dublin, Ph.D., New York, Vice President and Statistician.
William P. Shepard, M.D., San Francisco.
Third Vice President in charge of welfare work in the Pacific Coast Head Office.

IOWA PUBLIC HEALTH ASSOCIATION

The new officers of the Iowa Public Health Association, elected at the 18th Annual Meeting of that society in May, are:

President—Paul J. Houser, Des Moines
President-elect—C. L. Putnam, M.D., Des Moines
Vice-President—Hazel Roberts, R.N., Manchester
Secretary-Treasurer—Carl F. Jordan, M.D., Des Moines

AMERICAN INSTITUTE OF NUTRITION

According to *Science*, the new officers of the American Institute of Nutrition have been elected as follows:

President—Dr. Icie Macy Hoobler
Vice-President—Dr. William C. Rose
Secretary—Dr. Arthur H. Smith
Treasurer—Dr. E. M. Nelson
Councilors—Drs. Genevieve Stearns, T. H. Jukes, and C. A. Elvehjem

COUNCIL ON RHEUMATIC FEVER

A new organization called the Council on Rheumatic Fever, with offices at 1790 Broadway, New York, N. Y., has been created as a voluntary agency for promoting interest in and attention to rheumatic fever. Among the organizations represented on the Council are:

- American Public Health Association
- American Medical Association
- American College of Physicians
- American Rheumatism Association
- American Academy of Pediatrics
- American Hospital Association
- American Nurses Association
- American Heart Association

The new group was organized following action taken at a conference held in New York in January, 1944, at which the American Public Health Association was represented by David Rutstein, M.D., Deputy Commissioner of Health, New York City Department of Health, and Reginald M. Atwater, M.D., Executive Secretary, American Public Health Association. According to an announcement by the American Heart Association, under whose leadership the new group was organized, it is hoped that a fund of \$50,000 can be obtained within the near future to justify the selection of a director and the employment of an office staff.

Currently about \$7,000 is available, with another \$5,000 in sight. Negotiations are said to be in progress with officers of the American Legion in the hope that the Legion may accept responsibility for the financial support of the Council on a national scale.

The American Public Health Association will be represented on the Council by Dr. Rutstein and by George M. Wheatley, M.D., New York, N. Y.

FLORIDA OPENS EDUCATIONAL PROGRAM FOR FOOD HANDLERS

An announcement has been made that the Jacksonville Department of Health

(Fla.), in coöperation with the state and county departments, have begun "a perpetual food handlers educational program, to include a 12 hour course comprising 6 meetings 2 hours in length and designed to meet the practical needs of food handlers."

MICHIGAN BEGINS FLUORINE-DENTAL CARIES PROGRAM

Grand Rapids, Mich., has been chosen for a control experiment in dental caries under the auspices of the Michigan Department of Public Health, the U. S. Public Health Service, and the University of Michigan School of Dentistry, according to the *Journal of the A.M.A.* The experiment will include the addition of one part per million of sodium fluoride to the municipal water supply to determine whether reductions can be made in dental caries. The plan to add the fluorine to the Grand Rapids water supply was approved by the City Commission. Grand Rapids has been chosen because it has a stable population suitable for study over an extended period.

NEW YORK SYMPOSIUM ON FLUORINE AND DENTAL HEALTH

The New York Institute of Clinical Oral Pathology has announced an open meeting to be held in the New York Academy of Medicine on October 30 at 8:15 p.m. Among the contributors to the subject of Fluorine in Dental Public Health are Dr. Frederick S. McKay, Colorado Springs, Colo.; Dr. H. Trendley Dean, U. S. Public Health Service, Bethesda, Md.; Dr. Wallace D. Armstrong, Minneapolis, Minn.; Dr. Basil G. Bibby, Boston, Mass., and Dr. David B. Ast, Albany, N. Y.

MASSACHUSETTS INDUSTRIAL MENU AND NUTRITION SERVICE

The Massachusetts Division of Occupational Hygiene, in coöperation with the Associated Industries of Massachu-

setts, have begun what is intended to be a weekly menu and nutrition service available to Massachusetts industries.

The service is designed to aid managers of company-operated plant cafeterias by providing a carefully planned menu with suggested meal combinations that are nutritionally adequate and which observe ration allotments. The service facilitates the use of the cafeteria as an effective tool in a nutrition education program. Quindara Oliver Dodge is the Chairman of the Subcommittee on Industrial Nutrition of the State Committee on Public Safety, Boston.

W. K. KELLOGG FOUNDATION CREATES ADVISORY COMMITTEE ON PUBLIC HEALTH

An announcement has recently been made by the W. K. Kellogg Foundation, Battle Creek, Mich., of the appointment of advisory committees in three fields comprising its major interests to evaluate the present programs and activities, review the major financial requests presented to the Foundation, and to develop worth while activities in their respective fields. Committees have been named in public health, hospitals, nursing, education, and libraries. Committees in medicine and in public health engineering are planned.

The Public Health Advisory Committee consists of Wilson G. Smillie, M.D., New York, N. Y., Gregoire F. Amyot, M.D., Victoria, B. C., Henry F. Hemholz, M.D., Rochester, Minn., and Hugh R. Leavell, M.D., Louisville, Ky.

The Hospital Advisory Committee consists of James A. Hamilton, New Haven, Conn., Robin C. Buerki, M.D., Philadelphia, Pa., Basil C. MacLean, M.D., Medical Corps, U. S. Army, and John R. Mannix, Chicago, Ill.

The Nursing Advisory Committee consists of Leah Blaisdell Bryan, R.N.,

New York, N. Y., Minnie E. Pohe, R.N., Washington, D. C., Ruth B. Freeman, R.N., Minneapolis, Minn., and Lucile Petry, R.N., Washington, D. C.

INDUSTRIAL HYGIENE COURSE AT DE LAMAR INSTITUTE

H. S. Mustard, M.D., Director of the De Lamar Institute of Public Health, Columbia University College of Physicians and Surgeons, New York, N. Y., has announced that the Institute will offer an intensive course in industrial hygiene during the period October 30 to December 6, 1944. According to Dr. Mustard, the course will be so arranged that in any given week instruction will be focused upon one important phase of the subject and the students in the course may register for one or more weeks. The weekly schedule follows:

October	30—Dermatoses
November	6—Dust problems and hazards
November	13—Medical and surgical aspects
November	20—Plasticisers and solvents
November	27—Metals
December	4—Administrative aspects
December	11—Dental problems and services

Persons interested should communicate with the Director, 600 West 168th Street, New York, N. Y.

AMERICAN RED CROSS NAMES DR. DUBLIN TO EXECUTIVE POSITION

Dr. Louis I. Dublin, Second Vice President and Statistician of the Metropolitan Life Insurance Company, has accepted the position of assistant to the chairman of the American Red Cross, according to an announcement by Basil O'Connor, chairman of the Red Cross Central Committee. Dr. Dublin will be on loan from the Metropolitan for a limited period and will devote full time to his Red Cross duties, beginning October 1. These will include among others acting as coördinator of the various operating divisions and serving as liaison between the chairman and the operating vice-chairmen.

"Dr. Dublin has had long experience in public health work," Mr. O'Connor said, "and is almost as well known abroad for his services in that field as in this country. He served the American Red Cross in the first World War as a member of Red Cross commissions in Italy and in the Balkans. He has been President of the American Public Health Association, President of the American Statistical Association, and is now chairman of the board of the American Museum of Health. As Vice President of the Metropolitan in charge of public health relations, Dr. Dublin has taken active leadership in various campaigns for better public health and accident prevention. He has played a prominent rôle in raising the level of public health practices not only in official agencies but also in the operations of the voluntary health organizations."

As head of the Metropolitan's Statistical Bureau since 1911, Dr. Dublin has published many books and pamphlets on public health and on the economics of health. He has been called upon by the heads of many federal and state agencies to make health and economic surveys and to advise on various health projects. He served in 1942 on a commission appointed by Secretary of War Henry L. Stimson to study the operations of the Surgeon General's office, and in 1943 made a similar study for Surgeon General Ross T. McIntire of the Navy.

PERSONALS

Central States

A. C. BACHMEYER, M.D.,† Director of the University of Chicago Clinics, Chicago, Ill., was appointed to conduct a two year survey of America's hospital system at the initial meeting of the Commission on Hospital Care in Philadelphia August 1.

LEONARD C. BATE, M.D., Stambaugh, Mich., has resigned as Director of

Iron-Ontonagon County Health Department, effective August 15 to enter private industrial practice.

WILLARD G. BEATTIE, M.D., has been appointed Health Office of Ferndale, Mich.

RICHARD T. CAREY,† formerly with the Technical Department of E. I. Du Pont & Company, has joined the Laboratory Division of the Cudahy Packing Company, Omaha, Nebr.

GEORGE DONALD CUMMINGS, PH.D., M.D.,* has been appointed Director of the Bureau of Laboratories of the Michigan State Department of Health, succeeding the late C. C. YOUNG, D.P.H., who had served as laboratory director since 1919. Dr. Cummings is a graduate of the University of Michigan, Ph.D. 1934, and of Wayne University, M.D. 1943. He has been connected with the Michigan Department of Health Laboratories since 1926, serving in Grand Rapids, Powers, and Lansing. Recently he organized the diarrhea and enteritis study as a joint project of the Health Department Laboratories and the Kellogg Foundation. For two years he was Secretary of the Laboratory Section, A.P.H.A.

RALPH J. DORAN, M.D., U. S. Public Health Service, has been appointed to the Dayton Division of Health, Dayton, Ohio, as Venereal Disease Control Officer.

H. G. DYKTOR* has resigned as chief engineer of the Michigan Bureau of Industrial Hygiene, Lansing, after more than 4 years of service, and has been appointed chief of the newly created Bureau of Industrial Hygiene in the Division of Health, Cleveland, Ohio. Mr. Dyktor is Chairman of the Industrial Hygiene Section, A.P.H.A.

* Fellow A.P.H.A.

† Member A.P.H.A.

ROBERT E. FLOOD, M.D., Northport, Mich., has been appointed Health Officer of St. Joseph County, succeeding FREDERICK A. MUSACCHIO, M.D., M.S.P.H., who resigned to accept a similar position in Texas.

SIDNEY I. FRANKLIN, M.D., M.S.P.H.,* Newberry, Mich., has resigned as Director of the Luce-Mackinac County Board of Health.

F. G. GUNLAUGSON, M.D., M.P.H., has been appointed Director of Maternal and Child Hygiene in the North Dakota State Department of Health. Dr. Gunlaugson has been a County Health Officer in Minnesota, and is a graduate of the University of Minnesota in Medicine and in Public Health of Johns Hopkins University.

AWRA A. HOYT, M.D., who served as Health Officer of Battle Creek, Mich., for 24 years, resigned recently.

FRANCIS C. LAWLER, Sc.D.,* Professor of Bacteriology and Immunology, University of North Dakota School of Medicine, Grand Forks, N. D., was elected President of the North Dakota Public Health Association.

CLEMENT E. LOCKWOOD, M.D., Holly, Mich., has been appointed Director of the Alger-Schoolcraft District Health Department, succeeding HENRY H. ASHER, M.D.,† who died recently.

SAMUEL N. MALLISON, M.D.,† has been appointed to the new position of Superintendent of Health of the City of Decatur, Ill. Dr. Mallison will be in charge of the public health work of the city and assume much of the work formerly handled by PIERRE A. STEELE, M.D., City Commissioner of Public Health and Safety.

R. H. MARKWITH, M.D.,* Columbus, Ohio, who for the past 5 years has been Director of Health in the Ohio State Department of Health, has retired at the conclusion of his term and has accepted a position as Assistant

Medical Director of the Brown Clinical Laboratory, Columbus, Ohio. NEAL J. McCANN, M.D., has resigned as Health Officer of Ishpeming, Mich. CYRUS P. McRAVEN, M.D., Macomb, Ill., has been appointed Health Director of McDonough and Fulton Counties, succeeding the late EDWARD L. HILL, JR., M.D. Mount Sterling, Ill.

FRANCIS H. REDEWILL, JR., M.D., M.S.P.H.,† has designed as Health Officer of Sioux Falls, S. D., to accept a position as Venereal Disease Control Officer in the Los Angeles County Health Department, Los Angeles, Calif. His successor is EMIL G. ERICKSEN, M.D.,† who has been assistant to Dr. Redewill.

HUGH B. ROBINS, M.D.,* has been appointed Health Officer of the City-County Health Department in Battle Creek, Mich.

BENJAMIN WHAM, Winnetka, Ill., has been appointed Chairman of the Illinois State-wide Public Health Committee to succeed FREDERIC C. WOODWARD, LL.D., Chicago, Ill.

Eastern States

JAMES A. DOLCE, M.D.,† Health Commissioner at Wilmington, Del., has been appointed County Health Officer at Fairmont, W. Va. His successor is LT. COL. A. PARKER HITCHENS, M.D.

LT. COL. GARFIELD GEORGE DUNCAN, M.C., of Philadelphia, Pa., has been awarded the Legion of Merit by the War Department for his outstanding experimental work on the suppressive treatment of malaria in the Southwest Pacific Area. A native of Ontario, Colonel Duncan was graduated from McGill University School of Medicine in 1923. Prior to entering the service, he was Associate

* Fellow A.P.H.A.

† Member A.P.H.A.

Professor of Medicine at Jefferson Medical College, Philadelphia.

LT. COL. ARTHUR PARKER HITCHENS, M.D.,* Professor of Public Health and Preventive Medicine, University of Pennsylvania School of Medicine, Philadelphia, Pa., has been appointed Health Commissioner of Wilmington, Del.

FRED L. MOORE, M.D.,* who has been Director of the Division of Public Health Studies of the Commonwealth Fund, New York, N. Y., has been appointed to the newly established professorship of Social and Environmental Medicine in the Department of Preventive Medicine and Community Health, Long Island College of Medicine, Brooklyn.

LOUIS H. PINK, President of the Associated Hospital Service of New York, has been elected a member of the Board of Directors of the Visiting Nurse Service of New York. Mr. Pink is the author of a recent book, *Freedom from Fear*.

CAPTAIN THOMAS E. SHAFFER, M.C., U. S. Army, of New Haven, Conn., has recently been assigned to the Infectious Disease Control Branch of the Epidemiology Division, Preventive Medicine Service, Office of the Surgeon General, Washington. Capt. Shaffer is a graduate of Cornell Medical College in 1932 and was an instructor in pediatrics at Yale University School of Medicine in civil life.

LIEUT. R. S. TAGGART, M.D., formerly District Sanitary Engineer for the New York State Department of Health, has been appointed to a post in pest control work in the Preventive Medicine Service, Office of the Surgeon General, Washington, succeeding CAPT. D. F. SMALLHORST, SN.C.,† who has been assigned overseas.

FREDERICK A. WOLL, PH.D.,† Professor of Hygiene at the College of the City of New York and Director of the Department of Hygiene, has retired at the age of 70.

Southern States

OTTIS L. ADER, M.D., Walkertown, N. C., has been named Director of the Venereal Disease Clinic of the Durham City-County Health Department, succeeding ROY H. McDOWELL, M.D., Dunham, N. C.

WILLIAM O. BINGHAM, M.D., Roan Mountain, Tenn., has resigned as Health Officer of Carter County.

PAUL BRINDLEY, M.D., Professor of Pathology, University of Texas School of Medicine, Galveston, Tex., recently returned from a hospital tour in Costa Rica, Guatemala, Honduras, and Mexico City, where he had been making special studies in tropical medicine under the auspices of the John and Mary R. Markle Foundation.

MARION MURPHY BROOKE, Sc.D., Associate in Parasitology at the School of Hygiene and Public Health of the Johns Hopkins University, Baltimore, Md., has been appointed Associate Professor of Preventive Medicine at the University of Tennessee College of Medicine, Memphis, Tenn.

LT. COL. MARTIN A. COMPTON (MC), has been appointed a member of a board of the Office of the Surgeon General, Washington, D. C., the purpose of which is to prepare, develop, and implement the medical portion of the War Department's program for aid to civilian populations in liberated countries. This board was established in June, 1943.

JAMES P. CROLEY, M.D., Plymouth, N. C., has resigned as head of the District Health Department serving Tyrrel, Hyde, and Washington Counties.

EDWIN F. DAILY, M.D.,* Director of

* Fellow A.P.H.A.

† Member A.P.H.A.

the Division of Health Services of the Children's Bureau, U. S. Department of Labor, Washington, D. C., has been granted leave to serve with the Army of the United States to assist in reestablishing civilian medical and hospital services in some of the liberated countries.

JUDSON D. DOWLING, M.D.,* Sr. Surgeon, USPHS (R), Birmingham, Ala., has been assigned to the New Mexico Department of Health, Santa Fe, as Assistant State Director of Health.

ROBERT B. C. FRANKLIN, M.D.,† Mount Airy, N. C., has resigned as Health Officer of Surry County to enter military service.

JOHN C. HUME, M.D., U. S. Public Health Service, who has been serving as Venereal Disease Control Officer at Wilmington, N. C., has been detailed as Acting Director of the Bureau of Venereal Disease of the West Virginia Department of Health.

ERNEST W. PROTHRO, M.D.,† has been appointed Acting Officer of the Laredo-Webb County Health Unit, Austin, Tex., succeeding Arthur E. Ballard, M.D., who resigned to take a similar position at Belton, Tex.

PASSED ASST. SURGEON (R) ROBERT M. ROBBINS, M.D.,† formerly Director of the three northwestern county health departments of Walton, Okaloosa, and Holmes, Florida, has been transferred to Georgia and appointed as Asst. Commissioner of Health in the Macon-Bibb County Health Department, Georgia, as of August 1.

LT. COL. E. S. A. ROBINSON, M.C., A.U.S.,* Director of the Laboratory Division in the Office of the Surgeon General, has been appointed to serve on the American Red Cross Sub-

committee on Blood Derivatives and Plasma Fractionation.

JACOB LELAND TANNER, M.D., has resigned as Health Officer of Mercer County, Ky., to enter private practice of medicine in Henderson, Ky.

A. L. VAN HORN, M.D., has been appointed Director of the Division of Health Services of the Children's Bureau, Washington, D. C., to succeed EDWIN F. DAILY, M.D.,* who is on leave to serve with the Army of the United States.

LT. COL. THOMAS G. WARD, M.C.,† has been appointed Director of the Epidemiological Division of the Preventive Medicine Service, Office of the Surgeon General, Washington, succeeding LT. COL. ARTHUR P. LONG, who has been assigned to overseas duty. Colonel Ward is a graduate of Baylor University in medicine and has received the M.P.H. and Dr.P.H. degrees from Johns Hopkins University. He recently received the Legion of Merit award in recognition of outstanding services.

Western States

MILDRED T. WOOLLEY, DR.P.H.,† formerly Director of the Arizona State Laboratory, has been appointed Director of the Long Beach City Public Health Laboratory, Long Beach, Calif.

Foreign

BRIGADIER GENERAL WARREN FALES DRAPER, M.D.,* Chief of the Public Health Branch of Civil Affairs in the European theatre, was promoted by the Army to Major General, as announced by Supreme Headquarters in August.

ALFRED L. FRECHETTE, M.D., M.P.H.,† has returned to Concord, N. H., and has resumed his duties as State Health Officer after service as Surgeon with the U. S. Public Health Service in Africa.

* Fellow A P H A.

† Member A P H A.

Panama

PVT. ANATOLE SOLOW,[†] on duty with an Engineer Topographical unit in the Panama Canal Department, has received a letter of commendation from Lt. Gen. George H. Brett, Commanding General, congratulating him on the manner in which his lecture of July 26 on "Post-War Housing and City Planning" was received by the Panama Canal Natural History Society.

CLARENCE H. WARING, M.D., Medical Director, U. S. Public Health Service, has recently succeeded HENRY A. HOLLE, M.D.,[†] as chief quarantine officer of the Panama Canal Health Department.

Venezuela

MILTON LOPEZ HENRIQUES, M.D., Director of Local Health Services for the Ministry of Health of Venezuela, is spending two months with the State Health Department of Kentucky under the auspices of the Rockefeller Foundation.

Death

LOUIS A. JULIANELLE, PH.D., of 234 Mamaroneck Road, Scarsdale, N. Y., Chairman of the Division of Infectious Diseases of the Public Health Research Institute of the City of New York, Inc., since 1942, died on August 12.

CONFERENCES AND DATES

American Academy of Ophthalmology and
Otolaryngology. Chicago, Ill. October 8-12.

American Dietetic Association—27th Annual
Meeting. Palmer House, Chicago, Ill.
October 25-27.

American Water Works Association—
Southwest Section—Hotels Stephen F.
Austin and Driskill, Austin, Tex. October
17-19.

Missouri Valley Section—President Hotel,
Kansas City, Mo. October 23-24.

California Section—Biltmore Hotel, Los
Angeles, Calif. October 24-26.

West Virginia Section—Chancellor Hotel,
Parkersburg, W. Va. October 26-27.

New Jersey Section—Atlantic City, N. J.
November 2-4.

Four States Section—Benjamin Franklin
Hotel, Philadelphia, Pa. November 8-10.

Virginia Section—John Marshall Hotel,
Richmond. November 14-15.

Florida Section—Suwanee Hotel, St. Peters-
burg, Fla. November 16-18.

Association of Military Surgeons of the
United States. Hotel Pennsylvania, New
York, N. Y. November 2-4.

Civil Service Assembly—Conference on Public
Personnel Administration. Chicago, Ill.
November 1-3.

Federation of Sewage Works Associations.
William Penn Hotel, Pittsburgh, Pa. Oc-
tober 12-14.

Florida Public Health Association. Gaines-
ville, Fla. December 4-6.

Institute of Medicine of Chicago—Postgradu-
ate Assembly on Nervous and Mental Dis-
eases and War. Palmer House, Chicago, Ill.
November 1-2.

Michigan Public Health Association. Grand
Rapids, Mich. November 1-3.

National Chemical Exposition—Sponsored by
the Chicago Section of the American
Chemical Society. The Coliseum, Chicago,
Ill. November 15-19.

Public Health as an International Problem*

RAYMOND B. FOSDICK, LL.D.

President, The Rockefeller Foundation, New York, N. Y.

WE are meeting tonight in the midst of a cataclysm more ruthless, barbarous, and destructive than anything the human race has ever experienced. Military victory now seems assured, but the residual problems which this war will leave in its wake far transcend in difficulty and ominousness the problems which we have thus far faced. It is one thing to win a war; it is quite another thing, as we found in 1919, to win a peace. This war has unloosed hatreds and the desire for revenge so intense and so widespread that they will smolder long into the future. The evil consequences of what mankind has done in the last five years will be alive in the world when our children's children are carried to their graves.

Moreover, we know now, as we did not know in 1919, that modern war and modern civilization cannot survive on the same planet. We cannot keep both. One or the other has to go. We cannot have robot buzz-bombs and public health in the same world. We cannot

develop the destructive powers of physics and chemistry as they are being developed now and at the same time keep our schools and hospitals and cultural institutions intact. The bridges over the Arno in Florence are gone. How could we expect otherwise when men take dynamite and TNT into the heart of Florence?

As we look into the future the picture is frankly frightening. Let us not minimize it, or dismiss it with facile optimism. It is a picture of expanding physical power, of mankind armed to the teeth with increasingly destructive weapons as science and technology go forward on their triumphant march. We are faced with a question which we cannot dodge: Can that science and that technology be brought under control? Is man to be the master of the hurricane forces which he is creating or is he to be their victim? If science were standing still, if no new powers were to be added to those already in man's possession, the problem might eventually find solution. But, of course, the idea is fanciful. We are merely at the beginning of progress in our technologies. Physics and chem-

* Presented before the American Public Health Association at the Seventy-third Annual Meeting in New York, N. Y., October 3, 1944.

istry have barely got started in showing us what force really means. New powers and weapons are just around the corner, powers and weapons which the utmost wisdom could scarcely be trusted to use aright—airplanes larger, faster, and more deadly than those now employed, explosives capable of far-flung destruction beyond anything we dream of at the moment. How are we going to use these airplanes and explosives? How can we reconcile them with the progress and happiness of mankind?

Some years ago the organization with which I am connected—The Rockefeller Foundation—built a school of public health in Warsaw for the training of public health personnel. It is gone now—obliterated in the fraction of a second by a single high-power bomb. We built a school of hygiene and tropical medicine in London. The whole side of it, including the library, has been blown up. We built institutes of public health in Sofia and Budapest and Zagreb and Bucharest. Whether there is anything left of them today, we do not know. We built a library at the University of Nankai. It is completely demolished—not one stone left upon another. We built in Peiping the finest teaching hospital and medical school in all Asia. Whether any part of it will survive when the Japanese withdraw is anybody's guess.

But this is just bricks and mortar. Look at the situation from the standpoint of personnel and the training of intellectual leadership. For years The Rockefeller Foundation has been supporting work in the physical and social sciences at the University of Leyden in Holland and the three Czech universities of Prague, Brno, and Bratislava. Five years ago the Germans closed all these institutions and many of the professors and students were arrested and shot. Similarly the five Polish universities were closed, some of them were

destroyed and their faculties were dispersed and slaughtered. The University of Oslo in Norway must also be added to the list of bloody casualties. In France the University of Strasbourg, the Institute of Ethnology, and the Center for the Study of Foreign Affairs in Paris are only a random sampling of the institutions with which the Foundation has had a long connection and which have been suppressed with violence. In China what has happened to schools and universities is a story of brutality for whose counterpart we would have to go back to the Dark Ages.

What does it all mean? Are the efforts of one generation to be wiped out by the hatreds of the next? Must mankind look forward to having its schools periodically destroyed, its homes and cultural achievements periodically obliterated—with nothing that we cherish safe from peril, with no bridges over the Arno that can be guaranteed against human violence?

This is the kind of future we face. This is the problem that awaits us when the fighting is done. What are we going to do about it? We cannot go on as we have. Mankind has at long last come to the end of a road.

The answer is obvious, and it lies in the tentative beginnings that are now being made at Dumbarton Oaks. This country and the other countries of the world are confronted with a great decision, an insistent demand for the exercise of human intelligence on an unprecedented and daring scale. That decision calls for nothing less than the organization of the family of nations into an effective working unity. It means that we must marshal on the side of peace and fair play all the constructive resources to which access can anywhere be had—spiritual resources, educational resources, the common hopes of people in all countries, the ties that bind the human race together

across boundary lines, the innate decency of the masses of mankind when freed from perverted leadership, the hunger of plain men everywhere for justice and truth if only someone will tell them what they are.

This great effort to build defenses against our own violence cannot be a patch job. There is nothing now left to patch. It calls for bold and daring construction. We must be fearless in our devising, ready to scrap the shibboleths and catchwords about nationalism and sovereignty which betrayed us in 1919 and which for a century have cluttered up our thinking. We must be prepared for sacrifice, for nothing worth while is ever gained without it, and no nation can bargain itself into security. We must be ready to pool resources and assume responsibilities on a scale that will run counter to traditions and techniques which have long been cherished. In brief, we must be prepared for ideas and practices that may seem to some of us revolutionary, for the robot buzz-bomb is revolutionary and the new explosives that are on their way are revolutionary, and unless we meet revolution with revolution, we shall find ourselves overwhelmed by forces which are out of control.

The danger is that we shall do too little, that we shall be fearful of making too many concessions, timid about venturing too far, that we shall whittle away a strong plan in an attempt to compromise with a weak one, that we shall try to ward off a hurricane with merely a windbreak. Already voices of caution are being raised, and we are being warned that there are some steps that the United States cannot take without too violent a break with tradition. One of our more prominent columnists is talking about "the folly of challenging an ancient and cherished prerogative." But the robot airplane is challenging civilization itself and the possibility of decent human life on this

planet; and that, it seems to me, is far more important than the preservation of a cherished prerogative. Give us another ten years in the development of robot bombs and rocket guns and there will be precious few prerogatives left to anybody.

I do not have to suggest that the great decision which we and the other nations must make in the near future is bigger than any question of politics or partisanship. Any person or any group that tries to gain selfish advantage from this attempt to put international relationships on a stable basis is guilty of a crime which history will never condone. Let us be frank about the matter: We bungled a unique chance in 1919; this may be the last chance we shall have. What we do in this generation may well decide the kind of civilization, if any, which is to dominate the globe for centuries to come.

But what has all this to do with public health? In answer, I would say that no legal plan, no fixed formula, can by itself guarantee that the world will not be torn to pieces whenever passion and emotion gain the upper hand. The community of nations has got to have a kind of intellectual and spiritual integration before it can be absolutely sure that the forces of violence are under control. Consequently there must be developed for international life new areas and techniques of coöperative action which will fit the facts of the era upon whose threshold we are now standing. We need rallying points of unity, centers around which men of differing cultures and faiths can combine, defined fields of need or goals of effort in which by pooling its brains and resources the human race can add to its own well-being. Only as we begin to build, brick by brick, in these areas of common interest where coöperation is possible and the results are of benefit to all, can we erect the ultimate structure of a united society.

I think of public health as one of these rallying points of unity. Health is something that all nations desire, and no nation by the process of gaining it takes it away from another. There is not a limited supply of health for which nations must compete. Rather, every nation by promoting its own health adds to the better health of other nations, just as by assisting in the public health efforts of other nations we protect ourselves. Here in brief is a field of common interest to the race of man everywhere on the planet. Interpreted in broad, positive terms to embrace physical, mental, and moral fitness, it can be a nucleus of international activity which will encourage emulation in other and more difficult fields. What the League of Nations did in Geneva through its International Health Organization can be the starting point and basis of a far broader and better supported work. A world-wide epidemiological intelligence system, the standardization of biological products, the organized exchange of public health personnel to broaden the technical outlook and stimulate the imagination of health officers, the supplementation of public health activity in countries where it is inadequate, the development of minimum standards of acceptable public health work that can be applied on a world-wide basis, the creation of commissions of experts and international conferences on such subjects as malaria, yellow fever, rabies, nutrition, housing, rural hygiene, physical education, social security—these are only samplings of the activities which could profitably be pursued, perhaps on a regional basis, by a new International Health Organization. Activities of this type could develop new habits in international relationships. They could dig new channels of thought and establish fresh methods of approach. They could lead the way in showing the countries of the world, now separated

by hatreds and passion, what it means to play ball together.

* * *

Perhaps I have given the impression that the chief purpose of these activities in public health is the stimulation of an international unity which will save the world from shipwreck. That that objective is a challenging and fundamental aspect of public health work on an international scale I do not deny. But work in public health which disregards flags and boundary lines has become in our generation essential to the safety of the human race everywhere. We cannot have airplanes crisscrossing the world from every direction in the space of a few hours' time and expect to keep our old ideas of territorial sovereignty and our old methods of quarantine. Those ideas and methods have suddenly become obsolete. Public health can no longer be thought of exclusively in national terms. In a world as closely knit as ours, what menaces one country menaces all, whether it be disease or economic disaster.

Take, for example, the yellow fever situation. As you know, there has never been any yellow fever in India or in the Orient, although the chief carrier of yellow fever, the *Aedes aegypti* mosquito, is everywhere present there. Consequently no immunity against the disease has been built up, as it has been in continents like Africa and South America where yellow fever has long been prevalent. A country like India is therefore a tinderbox, ready for a conflagration of cataclysmic proportions. It would take only a single infected mosquito to break down all the barriers of quarantine, vaccination, and medical vigilance; and the airplane is ready at hand, able to carry insect passengers just as it carries human passengers. No nation by its own acts alone can protect itself from such an overshadowing menace. It requires united, coöperative action in

which boundary lines are overlooked and conceptions of sovereignty are relegated to the limbo of forgotten things.

The gambiae mosquito furnishes us with another classical illustration. Its home, as you know, is the African tropical belt, extending from the southern border of the Sahara Desert to the Zambesi River. For centuries it has been the scourge of Central Africa, a carrier of a serious and often fatal type of malaria. Until 1930 this mosquito was unknown on this side of the Atlantic. But a new line of planes began to bring passengers to Brazil and there was nothing to prevent the gambiae from coming along, too. And the gambiae came, with results so destructive that even today the terror of that visitation is deeply engraved on the memories of the inhabitants of northeastern Brazil. It took years of effort and millions of dollars to eradicate the species from its new home, but that result was finally accomplished, and it was hoped that the fumigation of incoming planes would prevent another incursion. But that hope was in vain. Last year live gambiae mosquitoes were found in dwellings near the Natal airport, and the beginnings of another conflagration were in the making.

Thanks to the efforts of the Brazilian and United States authorities, the immediate situation is now in hand. But it poses a problem of larger significance which cannot be evaded. The safety of the Western Hemisphere, now within a few hours' flight across a narrow ocean, can no longer be left to the uncertainties of a flit-gun campaign. If the Americas are to be protected adequately, the breeding places of gambiae, wherever in Africa or elsewhere they may be found, must be eradicated or controlled. The campaign must be carried to the sources of infestation. It can no longer be defensive; it must be offensive.

That campaign is now under way—at least the beginnings of it. Brazilian health representatives have been in West Africa, and American representatives are there today. Shades of the isolationists of 1919! What business has our official medical personnel in West Africa? Why can't we stay home and mind our own affairs? The answer is that this newly made world which the airplane has tied together has lost its frontiers. Whether we like it or not, the propinquity of modern life now confronts us with inescapable demands for new techniques. We are living in the 20th century and we cannot retrace our steps back into the 19th. For better or for worse we find ourselves in an era in which our only hope of survival lies in collaboration across boundary lines.

May I give one more illustration of the international character which public health must assume in this new world? The war is going to bring China into the forefront among the nations. A long and distinguished civilization and a great people are at last about to take their place among the leading forces of the world. In the near future, as soon as the war is over, the relations of the United States and the other nations with China will be close and intimate. We shall sell to her our refrigerators and farm machinery in exchange for the goods and services which she will provide; and easy access by plane and ship will promote the flow of ideas and cultural contributions back and forth across the Chinese border.

But China has a total of 658 hospitals for 460,000,000 people. In the United States there are more than 6,000 hospitals for 130,000,000 people. In China there is one well trained physician for every 70,000 of the population, whereas in this country there is one physician for every 750 of the population.

Even these figures only partially in-

dicating the magnitude of the need, because they do not take into account the fact that in China disease is so much more prevalent than it is here, and the conditions favoring its development are so much more acute.

Let us glance at some of the figures. Cholera is reported every year in China; there were 100,000 cases in 1932, 65,000 cases in 1942, 17,000 cases in 1943. Bubonic plague had approximately 6,000 cases in 1942. It is estimated that there are about 6,000,000 cases of dysentery annually, 90 per cent bacillary, 10 per cent amebic. The estimated number of cases per annum of typhoid fever is 700,000; of smallpox, 500,000; of diphtheria, 360,000; of scarlet fever, 180,000. Epidemic meningitis is estimated at 100,000 cases per annum; malaria, 21,000,000 cases per annum; schistosomiasis, 10,000,000 cases per annum. Active tuberculosis is estimated at 36,000,000 cases, 8 per cent of the population. Under-nutrition is so widespread that no figures of any kind are available.

Here is a country about to be linked by intimate ties with the rest of the world. Airplanes will establish new contacts and new trading centers at a thousand different points. The flow of goods and personnel will be a constantly rising tide. Does anyone say that the rest of the world has no legitimate concern and no responsibility for the health conditions of China? From now on, we shall be living in growing intimacy and increasing contact with those health conditions. I am not talking about charity, although I assume that this virtue is still valid. I am talking, rather, about the problem of trying to maintain a healthy life for ourselves and our children side by side with disease as rampant as it is in China. I wish that those who speak so glibly of

"globaloney" could see this picture of the international aspect of public health. In attempting to be hard-boiled and realistic they succeed in being merely unintelligent. The Levites of this world no longer have the option of passing by on the other side. They do so at their peril. In this inter-related civilization compassion for the man who falls among thieves has become an inescapable necessity. Whether it is malaria or cholera or plague or tuberculosis or whatever the disease may be, the nations of the world face these enemies of mankind not as isolated groups behind boundary lines but as members of the human race projected suddenly into a frightening propinquity. We did not plan it this way, and science did not plan it this way. We wandered unwittingly into this situation. But here we are—all nations and races jammed together into a single community, tied together by bonds which cannot now be severed. It is indeed one world—one future—one destiny.

* * *

Perhaps I have elaborated the thesis at too great a length. In a word, it leads to this conclusion: The day has passed when any one nation can live unto itself. It cannot even die unto itself, for the whole world would then be chained to a body of death from which mortal infection would flow to the rest. The hour for decision has come. Indeed it came twenty-five years ago and we are very late. We who are interested in public health have a challenging opportunity to lead the way, to lay one of the cornerstones of the new structure, to develop the thinking that must be done in expanding geographical terms, to serve the larger loyalties which must underlie this new world if it is to keep abreast with the facts of the 20th century.

Local Responsibility in Public Health Administration*

JOHN J. SIPPY, M.D., F.A.P.H.A.

District Health Officer, San Joaquin Local Health District, Stockton, Calif.

WHEN Dr. Underwood, in completing the duties of the President of the American Public Health Association, comes to the close of this three day conference and relinquishes the gavel, he will appear in a typical rôle, namely that of a state health officer indulging in the pastime of transferring an added responsibility to a local health officer. On that topic, you should know, we local health officers are given to more or less chronic grouching. We never weary of moaning about the multiplicity of new activities and duties which federal and state bureaus of health prescribe for us.

Perhaps, because our days are rounds of endless trivialities, which limit our horizon and obscure our perspectives, it is difficult for us to envision the panorama of purpose and plan of the general staff of nation and states, whose overall recognizance and knowledge of all sectors permit the planning and direction of our activities in coördinated fashion. We realize of course that a sound physical status for all of our population is a first requisite of national defense, and that each of our communities, as a part of the whole, must exert itself to insure this status. Nevertheless, at times we entertain fancies that we are the victims of an unfair division of labor, funds, and personnel.

We complain of the demands of increased population. Had normal conditions prevailed since 1940, some three or four millions of people would have been added to our local responsibilities. Instead, some twelve million persons in the armed forces, for whose health and welfare the federal government has assumed responsibility, have been subtracted from our concern. If, in certain areas where industries pertaining to the war effort have been intensified, there is some justification for complaint of the population overload, then it must follow that in many other areas there is population loss and one might expect lessening of local public health demands. In addition we must not forget that industry itself has assumed responsibility for the maintenance of health of several millions of workers who were formerly dependent on public agencies for health protection. One might mention other reliefs in population demands upon us. It is not, therefore, increased population of which we have a right to complain.

We speak of new public health problems. I doubt if we mean that, for on analysis, with only minor exceptions, there are no new problems. There are only new facets of old problems. Always mothers have had babies, always children have suffered from childhood infections, always large numbers of persons have been malnourished. Always, too, women have engaged in manual labor, and the fact that they have been

* Presidential Address delivered before the American Public Health Association at the Seventy-third Annual Meeting in New York, N. Y., October 3, 1944.

transplanted from the drudgery of home and field to the mechanical processes of industry does not necessarily bespeak greater physical hazards or deterioration. What we do mean by new health problems is only a clearer recognition of old ones and a call for greater application of effort toward solution of them.

Several decades ago it was obvious that national and state public health agencies were not in position to apply public health measures in practical manner. To explain, it has been said that public health is the sum total of the health of individuals. The education which produces it is therefore something which cannot be supplied to the populace in carload or truckload lots from national or state capitals. It must be dispensed to individuals in ounces, drams, and drops, and its dispensing to those who need it must be insured. This must be done by the local agency who can know how, when, and where individuals can be reached, and who can inspire the local community to want and to support facilities necessary to its general health preservation. It cannot be done in strict accord with any set pattern, for each community has its own characteristics and customs which no transcendentalism or government fiat may affect. It must come from local, voluntary reaction.

Our states are made up of various units of local government. Our democratic form of government presumes that these shall be granted every privilege of local self control, and it is only when they fail to exercise it properly or when they infringe upon the rights of other units that the state is justified in intervening. This is as true in the preservation of public health as in the preservation of law and order. More so, for since communicable infections have no respect for political boundaries, and since no unit may tolerate the prevalence of contagion within its jurisdiction without endangering the health

and lives of citizens of adjoining units, it is more than a privilege of local control; it is a duty which the state must insist be performed. It has insisted by enacting legislation granting to the various units police powers for the protection of the public health and making it mandatory that they exercise these powers.

This mandate however often fails to envision the whole of the modern public health movement and, for the most part, applies only to the control of communicable diseases or of insanitation. While few local units wilfully evade it, there are far too many which have failed, either through apathy or lack of means, to provide proper facilities for carrying out their obligations, secure in the belief that they may in emergency rely upon state agencies.

Lack of means is the greater deterrent of the two and is often more imaginary than real, for while we public health workers may clearly realize justification for public health expenditures it is not easy for many taxpayers to do so. We are irked by their lethargy and impatient with their delay in acceptance of our promises of the benefits of efficient health services, forgetful of the old adage concerning persons "convinced against their will" and that it is only through their spontaneous conviction and coöperation that the services we propose will be utilized.

Sometimes such communities are convinced by emergency, sometimes by demonstration. The basis of the demonstration method, originated by voluntary organizations and by several of the foundations interested in stimulating public health procedures, is that of a financial incentive or grant-in-aid for a temporary period. By reason of many successful demonstrations it has become a federal philosophy which promises complete permanency. A grant-in-aid for public health purpose in those communities burdened by activities of

national import, the cost of which should be distributed over the whole nation, appears most justifiable. Likewise it appears a necessity in those communities with actual lack of means. Perhaps we can agree that it serves a useful purpose in broadening the scope of activities of all public health departments until these activities become accepted as a local responsibility or until local means of support become available. We may also agree that its use can result in a general uplift of public health standards, even though it may be debatable as to whether all communities require or demand the same quality or quantity of such services.

It is very easy for those of us who have had to contend against the old-time penuriousness in public health expenditures to become overly enthusiastic about grants-in-aid. But already state health officers are rumoring that formerly self-reliant communities are substituting these grants for tax funds previously levied for support of many local health activities in order to divert such tax funds to other purposes; that other communities threaten to discontinue proven, needed activities if grants-in-aid are not forthcoming; that still others are demanding these grants, not as a need, but as a right.

There is evidence that in some communities these grants are encouraging public health patterns much too large for the cloth and in excess of the community needs and resources. There is also the attendant danger that because of their source, local taxpayers feel no concern as to the manner in which they are expended, a fact which may lead to extravagances and waste, discrediting the wisdom of all public health expenditures and the business prudence of health officials. We as friends of pub-

lic health progress must insure that a grant-in-aid shall be used only as a gentle stimulant and not as a narcotic which soothes its victim to complacency and contentment while its effects last, and sends him into collapse when it is withdrawn.

That, thus far in the dispensing of these grants, there has been no grave evidence of usurpation or obnoxious autocratic direction of local health activities, has been due to the integrity and sincerity of federal and state officials who administer them. It must be remembered however that present policies may fluctuate and in this fluctuation there is inherent danger. The power to give implies the power to take away. If we in local communities permit ourselves to become so wholly reliant upon these grants that withdrawal of them means catastrophe to our cause, it means that we may yield to centralized bureaucratic control. While this may be for our betterment, it is repugnant to our democratic ideas and ideals.

Much depends therefore on the degree to which we permit our communities to become dependent upon these grants. They do not depend upon them for support of their public schools or fire and police departments. Is protection of the public health a lesser responsibility? Our public health education can be regarded as failure if it cannot teach our people the value of community supported and controlled local health activities which meet their wishes and supply their needs. Neither individuals nor communities can continue to accept unwarranted contributions without sacrifice of character. We too must anticipate the possibilities of ultimate readjustment and reconversion.

A Coördinated School Health Program

MAUD A. BROWN

Director of Health Education Service; State Board of Health, Helena, Mont.

IN organizing or reorganizing a program of community health education it matters not from what field the initiative comes, the promotion inevitably will devolve upon the group stronger in local leadership.

In Lewistown, Mont., this meant the schools since there was at the inception of the program no organized health department in the sense that it now exists as a County Unit. The school system on the other hand had for two generations been a compactly organized and authentic factor of community living. This advantage being coupled with a fortuitous leadership in the school administration, it is not difficult to understand that the present County Health Unit, strongly educational in character, grew out of the school interest in health education.

That this incursion of education into public health education is not resented was indicated by the election of C. G. Manning, Superintendent of the Lewistown Public Schools, as President of the Montana State Public Health Association, following an address telling of the program briefly described in this article. The President of the State Medical Association voiced the approval of his group "without reservation, of the principles and procedures involved." It would seem that real coördination is in sight.

Lewistown is a central Montana city of some 6,000 people. It is the county seat of Fergus County and the center, professional, educational, and commercial, of a large ranching area, extending well beyond the boundaries

of the county. Fergus County itself covers an area of 4,250 square miles, about the size of the state of Connecticut, giving each of its 8,000 citizens outside the county seat, on the average, half a square mile of territory.

The program here described was developed in coöperative planning with the Health Education Service of the Maternal and Child Health Division of the Montana State Board of Health.

The planning began, to quote Superintendent Manning, "with progress in our own thinking," the outcome of this thinking having been the shifting of focus to functional health of the individual child and the recognition that this can be achieved only by way of the home, which in turn is conditioned by the total community environment.

In making plans for this vitalizing and socializing of the school health program the least privileged communities were kept ever in mind and problems and procedures reduced to the lowest possible terms. But never below the irreducible minimum of health essentials.

The preliminary planning involved three steps: (1) identifying these irreducible minima of healthful living; (2) determining whether these essentials fall within the resources of an ordinary school system in an average community; and (3) deciding what changes in the existing local school situation were necessary to make school living really a continuous optimal experience.

When faced squarely, pencil in hand, ruthlessly setting down in two categories those practices "essential to

health" and those "not essential to health" (although perhaps socially desirable), the column of essentials emerged reassuringly short:

1. Food, clothing, and shelter which are health permitting
2. Protection from physical hazards of disease and accident
3. Protection from mental and emotional hazards

No one was willing to concede these to be out of reach of the American child in general, or the Lewistown child in particular.

COMMUNITY ENVIRONMENT

The first problem then became: Can Lewistown provide adequate food, clothing, and shelter for its children and protect them from physical and social hazards? This involved a study of the social structure of considerable significance. The findings were set forth graphically by means of the Russell Sage Foundation social survey symbols glued in place on a large map of the city.

Analysis indicated incoördination to be the key difficulty. Whether the 64 organizations and four coördinating groups are typical of the small American city is not within the scope of this study to determine. Certainly no element ordinarily encountered in community living seemed to be unrepresented in this town of 6,000 people.

SCHOOL ENVIRONMENT

The school environment was next made the subject of careful scrutiny, that it present no essential health hazard.

1. *Physical Environment*—A survey of the school plant was conducted by the physics classes of the high school. This study covered lighting, ventilation, temperature, sanitation, seating, and safety conditions. This responsibility was assumed in all seriousness by the pupils, and their findings and recommendations were made actual use of in

the final plans for the health permitting school environment.

All conditions immediately detrimental were corrected at once, and improvements which did not entail great expenditure were made. Ventilation was improved by placing grilles in doors, windows, and walls; playground surfaces were improved; more attention was given to window shades, sanitation, toilets, redistribution of seating, etc.

A long-time program of major changes was next set up. This program has been carried on steadily until it is now virtually accomplished. First the citizens voted several thousand dollars for major changes. These included new toilet fixtures, new plumbing, and increased water supply in two buildings; new roofing for two buildings, new blackboards to conserve eyes, new shades for one building to improve lighting; new lighting fixtures in some rooms requiring considerable artificial light during the school day; new walks to increase safety; new walls in and about boiler rooms; changes in wall decorations to improve lighting and appearance; changes in the treatment of floors to improve sanitation, safety and appearance.

2. *Social Environment* — In the schools the interrelationship of mental, physical, and social health was already understood and its essential nature appreciated. Special consideration was given at P.T.A. meetings and conferences to encourage the home to assume its rightful responsibility for the health and social activity of its children.

A healthful social environment within the schools was promoted by the general teacher attitude and in the high school by the work of the special departments of vocational guidance, and physical education, working together with a trained personnel director. A course in social relationship was already being given as part of the social science curriculum in the high school.

In the beginning of the present program of threefold health, a survey of student opinion in the high school was made relative to personal social problems and the kinds and amounts of social activities desired. These opinions served as criteria for evaluating the social environment at school, and a guide for adjustments.

In the junior high school social activities in judicious amounts were introduced and special effort was made to secure participation by boys and girls who found difficulty in making social adjustments.

3. *Curricular Environment*—A survey of pupil load was made, in order to avoid either extreme, the overcrowded and overstimulating curriculum, or the unchallenging one. In the high school overloading appeared as the most serious among the conditions discovered. To obviate these curricular hazards, the programs were checked and a more personal guidance program instituted which included all classroom teachers as well as the two specially trained staff members.

The elementary school curriculum presented only one specific danger, fatigue. This danger is inherent in the plan of organization, a modified platoon, particularly when the work with special teachers begins with the first grade as was the case here until last year. It is the greater when teachers keep the children on their toes with interest as they do in Lewistown. The teachers consciously planned to counteract this recognized tendency not by making their teaching less interesting, but by definite and frequent relaxation periods.

THE SCHOOL HEALTH PROGRAM

The prerequisite of the actual essentials of healthful living at home and a safe school environment being planned for, the school health program presented the basic three-part organiza-

tion: health service which puts the child in as nearly optimal condition as remains possible to him; health supervision, which keeps him so; and, *finally*, health instruction which renders him progressively self-supporting in health. While it is impossible to separate these three aspects of any school health program, the major responsibility rests as follows:

Service—physician assisted by nurse and to some extent by teachers

Supervision—nurse assisted by teachers

Instruction—teachers assisted by nurse and physician

I. HEALTH SERVICE

From the first, the goal of the full-time county unit was held steadily in mind by local and state personnel. The President of the School Board (who was also part-time city health officer) and the Superintendent of Schools had already been quietly promoting the county unit, and had worked out details of a plan for pooling the funds allotted to health by the county, city, and school district, and the fusion of personnel. This plan was adopted later on in the working out of this program to the advantage and satisfaction of all concerned. At the beginning of the program the city and county health departments were separate, each under a part-time health officer who took part time from his local practice. One "school nurse" was paid jointly by the City School District and the State Board of Health. She was doing traditional school nursing and was responsible directly to the Superintendent of Schools. As reorganized, the services of the county, city, and school district are fused and this county unit is directed by a full-time health officer.*

* Since the regrettable death of the Director of the County Unit, a suitable full-time health officer has not been found, and the service is temporarily in charge of a local physician with public health experience who, however, is unable to give more than half time from his private practice. Every effort is being made to secure a competent full-time man.

A second public health nurse was added and the service of the two generalized, one serving the city and the other the rest of the county. The field of the city sanitarian now includes the entire county and the county physician serves also the city, according to a coöperative plan with the County Medical Society.

The work of the Fergus County Health Unit is the same in scope as that of the other units described in the *Report of the Montana State Board of Health* for the last biennium. All serve the schools as elements of the community organization, the director of the county unit being in each case the director of the school health service. This paper is concerned with the way in which the school district of Lewistown has worked out its problems of orientation within an integrated community health program.

THE TEACHER'S HEALTH

The most unusual feature of this school health service is that it starts with the health of the teacher. After some experimenting the following plan was adopted and works to the satisfaction of teachers, administrators, and physicians.

Every teacher is given a complete physical examination once a year, by the physician of her choice at a fee (\$5) determined by the local medical group and paid to the physician by the Board of Education from school funds. The completeness of the examination is insured by the use of the form prepared for teachers of the state by Director of the Maternal and Child Health Division of the State Board of Health. This form is filled out during the examination and given to the teacher, the only report going to the Superintendent's office being a slip saying that the physician considers the physical condition excellent, good, fair, or poor; that examination does or does not reveal

conditions which render the teacher's occupation dangerous to those about him or her; whether modification of program is recommended in the teacher's own best interests; and whether further medical care is recommended. No one but the teacher himself or herself sees the specific findings of the examination.

The teacher's health is further safeguarded by sick leave on pay; a reasonable teaching load; a somewhat higher than average salary schedule, no distinction being made between elementary and high school pay or educational requirements; a state retirement fund; a real right of free speech; opportunity to grow in service giving a wholesome feeling of accomplishment and security.

THE PUPIL'S HEALTH

1. *Periodical Physician's Examination*—

The director of the county public health unit makes an annual routine examination of the pupils of the five grades—1, 4, 7, 9, and 12, and all entering pupils.

The presence of parents is insured by scheduling the parent and pupil for a definite hour, which the physician takes pains to meet. The nurse makes the appointment with the mother. Since the time is adapted to their convenience, a very high percentage of mothers are present.

Uniformity of examination and consistency of recording are furthered by use of the form on the cumulative health record, prepared and furnished free on request to the schools of the state by the State Board of Health. Since issuance a year ago, its use is spreading rapidly.

The teamwork of the nurse and teachers in the follow-up of the recommendations is described under health supervision. In cases where pupils are unable to pay for service recommended, the Board of Education may pay from

school funds when the county physician or a voluntary organization has not been able to take care of the child's need. A considerable number of bills for glasses, dentistry, tonsillectomies, and supplementary food have been met by the school district.

2. Immunization—

Every effort is being made to secure protection against diphtheria and smallpox in infancy. Those pupils not yet protected or who for some reason are not referred to a family physician are immunized on entrance as a part of the school health program.

3. Mantoux Tests for Tuberculosis—

These are given routinely to all first year students in grades and high school, and to all new students. X-rays are taken of all reactors. Follow-up of all cases and of contacts is a part of the health supervision exercised by the public health nurses.

4. Emergencies—

The director of the unit is on call for accidents or sudden illness serious enough to need immediate medical attention.

5. Dental Service—

Dental service is on the private office basis. Dental referral cards are sent to every home at the first of the school year urging the parents to take the child to the family dentist. A report back to the school is requested of the dentist, and cards are supplied. The referral cards with the form for reply are furnished free by the State Board of Health.

6. Nursing Service—

The bulk of the work of the nurse in behalf of the school child falls under supervision in our threefold division of the school health program.

Certain of her functions, however, fall logically under service:

Assists the doctor in the periodical examination at school

Assists in giving inoculations and vaccinations, and Mantoux tests

Holds routine interviews with all pupils referred by the teacher

Makes routine inspection of all pupils of the grades not examined by the doctor

Answers emergency calls in case of injuries and illnesses at school

Includes the school age child in all phases of her family service, giving sick care when necessary, thus being sure that in protecting the health of the school age child she is not overlooking health situations in the home which influence the child's health

Also includes maternity, infant, and pre-school service in her generalized program so that every effort is made to insure optimal health for the children who enter school at the age of 6 years

7. Nutrition Service—

Conditions have changed radically and rapidly during the period covered by the program. In the beginning the need for food was still acute and the WPA facilities were made use of during the first two years. The education of the pupil and parent was meanwhile concentrated on by nurse and teacher and county extension agent. Finally the combination of education and improved economic conditions in the home seemed to indicate that the emergency phase of school feeding might be considered past, and only the two procedures considered an essential part of any permanent school health service were retained.

a. Mid-session milk for those who in the judgment of the nurse and teacher would profit by extra nourishment, or those whose parents request that they have it. The judgment is based on the knowledge of the total food intake of the child. Because of the intimate knowledge of the pupils shared by the nurse and teacher, this knowledge may be considered unusually reliable.

b. Noon lunch for pupils who live too far away to go home at noon. In the 6 elementary grades one hot milk drink or milk soup is provided to supplement the packed lunch. In high

school a balanced hot plate and drink are served at exact cost.

Last year all school feeding was discontinued, tentatively. This was for three reasons: (1) it was becoming increasingly difficult to obtain help; (2) the turnover of teachers became so acute that anything outside the classroom teaching procedures took on extraordinary difficulty; (3) the most cogent, it seemed possible that the new prosperity which places adequate food within the financial reach of practically all families afforded the strategic opportunity to return the responsibility of feeding their children to the home. The school participated in an educational program carried on by the County Nutrition Committee, the aim of which was to prepare the mothers more adequately to assume this responsibility. It was evident, however, that there does exist an educational aspect of school feeding and that mid-session milk and a hot drink or soup with the carried lunch constitute features of the irreducible minimum of any school health program. It is definitely planned to reinstate these as a permanent feature of the school experience.

Thus far the war has not made serious changes in the food intake of the children of this community. Plans are being formulated to take care of the inevitable shifting and shortages which have come a little more slowly to this ranching and dairying county than to some other regions.

II. HEALTH SUPERVISION

It is impossible to separate supervision from service on the one hand and instruction on the other. The nurse is therefore inextricably bound up with the work of those who serve the child in the two professional groups—health and education. She is the key person in any public health program.

In the Fergus County Health Unit, one of the two nurses is assigned to the

City of Lewistown which has a population of about 6,000. Naturally there is not much time for individual supervision of the child at school. Through her maternal, infant, and preschool program, the school child is served most effectively before he becomes a school child. Supervision of the school children at school is carried on chiefly through the teachers who have them under observation in small groups every day. The collaboration of nurse and teacher is so effectively worked out that it constitutes the most distinctive feature to date of this school health program. The fact that the functional interpretation of education is really accepted by these teachers makes health instruction which fails of application a recognized absurdity. Thus, teacher and nurse are brought together from their specific fields in a complete fusion of effort. The joint function, for want of a better term, is referred to as health supervision.

The Personal Folder—In this school system individualization had been developed to such a degree that a personal folder follows each pupil from kindergarten to high school. In the year of the beginning of the present health program, the first folders started in kindergarten had reached first year high school. It was a vehicle providentially at hand for the addition of, or rounding out of, records of physical health.

These folders in the elementary schools are kept in the desks of the classroom teacher where they are in constant use. In the junior and senior high schools, they are filed in administrative offices, readily accessible. At present the data routinely included are:

a. Cumulative health records carrying personal information from the kindergarten through the high school. Upon this form the findings of the medical examinations are recorded and all notations by physician, dentist, nurse, teachers, and social workers are

transcribed in condensed form. Emotional health is included and sufficient information regarding school progress to give a picture of the child as a functional unit.

b. All records, scholastic, social, and physical, other than those contained in the cumulative health records.

c. Copies of teachers' letters to parents, parents' notes to the school, and notations regarding conferences with parents or others concerning the pupil.

d. The teacher's yearly informal summarizing reports of the child.

The Nurse-Teacher Work Sheets—The implementing instrument for utilizing this fund of information about the child is the nurse-teacher work sheet. This is a detailed form upon which are checked for each pupil the specific goals for health improvement toward which the effort of teacher and nurse are to be directed. It is doubtful if dissipation of effort can be prevented without the focus that a common work sheet gives. At the end of every school year the year's health history as recorded on the work sheet is summarized and entered on the cumulative record. At the beginning of his next school year, new ones are prepared for the continuation of combined effort toward specific improvements. It is only as a result of itemized efforts that the cumulative result of improved general health can be achieved and the child's total condition raised progressively nearer and nearer the optimal.

After the first year's use of the nurse-teacher work sheet a plan was worked out obviating the duplication for the teachers of this work-sheet and the personal record already routinely kept by the teachers. The plan has proved satisfactory to all concerned.

Routine of Collaboration—The effectiveness of health supervision in the schools depends primarily upon the division of labor between teacher and nurse. With increasing demand for

nurses in defense, and the multiplicity of extracurricular demands upon the teacher, this becomes increasingly important. Each has her peculiar field within which her contribution is most effectively and most economically made.

It is agreed by all concerned that in the generalized service the school child is served most effectively as a member of the family unit. In conserving the time of the nurse it is most important to minimize the time spent on the school premises.

The Lewistown plan was worked out by the elementary supervisor and the present public health nurse. It omits entirely the routine visit of the nurse to the school.

Visits on behalf of school children are made on request of teacher or principal on a "request for nursing services" form. These forms are filled out every morning and placed on the principal's desk in each building. The elementary supervisor collects these every day in her rounds, and leaves them on the nurse's desk in her office. At the same time she takes up the slips left previously on which the nurse has written the report of the call including the requested information. This plan works simply and smoothly and, most unusual of all, promptly. Teachers for the most part have this report the next day. The nurse's time is conserved for her professional services.

Needless to say, the nurse is not concerned with attendance except where health problems are involved.

Emergency calls are telephoned direct to the nurse's office. These are becoming increasingly infrequent with teachers' growing ability to deal with situations and the elimination of safety hazards from the school plants.

Since the nursing service is generalized, every visit, however initiated, is a complete visit to the family as a whole.

Conferences at School—The time of the

nurse is conserved by the readiness of parents to come to the school to talk over all manner of problems. Many a home visit is obviated by a school conference with the mother, and many a visit is made unnecessary by the principal and teacher including health as a matter of course in their conversations with parents.

Last year the scheduled parent conference took the place of the monthly letters to the home. (The school system had long since discarded the report card with its formal grading.) Defense activities recently have interfered with this scheduling of conferences so that the informal letters are substituted when the personal conference is not practicable. Health takes its place in the unit picture of the child under consideration thus, incidentally, reducing still further demands on the nurse's time. The cumulative health record, and the nurse-teacher work sheet afford definite data for the teacher in these conferences.

The unscheduled parent conference, however, is more important, and indicates a rapport between the school and home which makes possible the general response to the regular conferences. It was this very unusual freedom of intercourse between school and home that gave first indication to the new Health Education Service that here was fertile soil for a proving ground. The Parent Teachers Association is a going concern and the freedom of discussion of common problems takes the place of much individual discussion.

Education of Teachers in Service—The proposal of this more active rôle of the teachers in personal health supervision brought a certain amount of uneasiness on their part as to whether they were qualified to form judgments in this field.

The local medical group was requested to give a series of talks to the teachers on the characteristics of health

in childhood and the essentials of healthful living. One lecture was illustrated by children chosen to demonstrate prime condition. In addition to the reassurance these lectures gave the teacher, the giving of them fostered a spirit of sponsorship in the medical group.

Health literature was furnished each building for the teachers' use. Textbooks on the college level in personal and public health were bought, *Hygeia* was subscribed for, and lists of reference material for loan and for free distribution by the State Board of Health were supplied.

The most important assistance for the teachers came, as always, from the nurse. In her frequent and friendly contacts they found an ever present help, and feelings of insufficiency were short lived.

III. HEALTH INSTRUCTION

The more completely integrated a program is, the more difficult an organized presentation. The work of the classroom teacher in health supervision merges so completely with the application phases of health instruction that much of the discussion would be appropriate under either head. Particularly is this true here where all instruction is on the unit activity basis, that is, is functional in aim.

Health is taught here as a basic scientific body of subject matter with the aim of developing a recognition of and respect for cause and effect which will result in present application of the facts taught and in successful adaptation to changing conditions.

Present space precludes discussion of teaching procedures.

The most critical year of the program described above lies just ahead. The school year 1944-1945 opens after two years of war have made inevitable inroads upon the program described above, but since the planning had been

from the first in lowest terms, with the participation of the whole citizenry provided for, the war emergency has been less destructive in its effects than might have been feared. There has been compensatory increase of effort in some directions which partially offset the depletion of human resources in others.

Most serious of all is the diminished medical service and the consequent overwork of the nurses, sanitarian, and all who in any way can carry a fragment of the physicians' load. The examinations of school children have been discontinued. The annual examination of teachers is carried on as usual, but more hurried in some cases, as the pressure on the doctors increases. The incidence of communicable disease has increased as it has throughout the state.

The increased responsibility assumed by the home and the teachers, however,

has gone far toward compensating for the lessened professional service. While there are no numerical data, the consensus is that noncommunicable illness has decreased.

The children are reported as being definitely better fed, and the mothers more appreciative of the help of the home demonstration agent, the social worker, and the visiting nurse. The teachers are taking over more of their rightful rôle in guidance, and the time of the public health nurses is thereby still further conserved.

The encouraging feature of the situation is that the responsibilities being assumed by the school and home are coming to be recognized as their rightful prerogatives and not to be relinquished when the technical health services are restored. With the post-war return to pre-war staffing, a greatly increased effectiveness is to be expected.

Typhoid Vaccine Studies IX

Intracutaneous versus Subcutaneous Vaccination for Initial Immunization

MAJOR GEORGE F. LUIPPOLD, S.N.C.

Chief, Division of Typhoid Research, Army Medical School, Washington, D. C.

IN 1939, Siler and Dunham¹ published a preliminary report on the re-immunizing effect of 0.1 ml. of vaccine intracutaneously administered. During the following year, Longfellow and Luippold² reported results on an extension of the preceding work.

Since this time, it has been asked why the intracutaneous route for the establishment of *initial* immunity has not been adopted, inasmuch as it had been recommended for revaccination. The answer, of course, is that, although there is a mass of clinical and experimental data on the effectiveness of subcutaneous vaccination, there are no comparable data on the efficacy of vaccination by the intracutaneous method. Realizing the capacity of the skin to produce antibodies, an investigation of dosage and routes of administration of typhoid vaccine was begun here early in 1940, but this study was interrupted by the intervention of other and more urgent work, and was postponed until time and material again became available.

Meanwhile, we had made an observation on a diminutive-scale comparison of these two methods of vaccination. During the latter part of 1942, we received specimens of serum from Morgan³ as control material on other sera included in an investigation being conducted by him at that time. Eight of the control sera were from persons who

had been inoculated intracutaneously with 0.05, 0.1, and 0.1 ml. of commercial T.A.B. vaccine, while 7 were from individuals who had received 0.5, 1.0, and 1.0 ml. of the same vaccine subcutaneously. The sera of these 15 persons were titrated for protective substances⁴ active against *Eberthella typhosa*. Results of these titrations have been recorded in Table 1.

TABLE 1
Results of Serum Protection Tests on Small Groups of Individuals Vaccinated, Respectively, With an Intracutaneous Course of T.A.B. Vaccine Consisting of 0.05, 0.1 and 0.1 ml., and with a Subcutaneous Course of 0.5, 1.0, and 1.0 ml.

Minimal Lethal Doses of Test Organism	Number and Per cent of Persons Whose Sera, in 0.1 ml. Amounts, Protected Groups of 4 Mice Against the Doses of Test Organisms Listed in Column on left			
	Intracutaneous Group		Subcutaneous Group	
	No. of Persons	Per cent	No. of Persons	Per cent
(<i>E. typhosa</i>)				
100,000	2	28.5
10,000	3	43.0
1,000	2	25.0
100	4	50.0	2	28.5
10	2	25.0
Totals	8	100.0	7	100.0

If these results were any indication of what would happen in large groups of individuals, it was plain that intracutaneous vaccination is definitely inferior to the subcutaneous method—in the dosages used. Morgan and his

associates³ commented on this observation as follows: "The intradermal administration of bacterial vaccines was found less effective than the subcutaneous route." As will be shown later, dosage is an important factor; and to have added "in the dosages used" would have been a desirable qualification.

Meanwhile, also, we were aware of an increasing tendency toward intracutaneous administration of typhoid vaccine by many agencies, for the establishment of initial immunity. The most interesting report of this activity appeared under the heading of "Vaccination: Wholesale," in which Fennel⁵ wrote of the widespread practice of intracutaneous vaccination of the civilian population of Hawaii by the local health authorities. This incident in Hawaii has also been revealed in the introduction to a paper by Tilden and Arnold.¹⁵ The popularity of the intradermal method of antityphoid vaccination in Cuba has been commented upon by Curbelo,¹⁷ and more fully expounded in a paper by Argudin.¹⁶

We were also aware of the many reported studies on the comparative effectiveness of intracutaneous and subcutaneous vaccination; but all of these, with the single exception noted below, were evaluated on the basis of agglutinative titers, whereas we desired an evaluation based upon the production of demonstrable protective substances in the blood serum.

Tuft⁶ (1931) advocated as a routine procedure the intracutaneous administration of 4 doses of triple typhoid vaccine (0.05, 0.1, 0.15, and 0.2 ml.) spaced by an interval of from 5 to 7 days. At this time, his conclusions were based on the results of agglutinin titrations; but in 1940, Tuft⁷ reported the results of mouse protection tests with pooled sera from 9 individuals who had been vaccinated intracutaneously with 3 doses of typhoid vaccine (0.1, 0.15,

and 0.2 ml.) at weekly intervals. The protective titer of this pooled serum was reported to be somewhat higher than that of a pooled sample of serum from 19 subjects who had received 0.5, 1.0, and 1.0 ml. of the vaccine subcutaneously. Tuft then recommended the 3 intracutaneous injections cited above as routine procedure.

Valentine, Park, Falk, and McGuire⁸ (1935) reported on the agglutinin response produced by intracutaneous and subcutaneous vaccination, concluding that the intracutaneous doses employed were as effective as five times the amount of vaccine subcutaneously administered, but that one-tenth of the subcutaneous dose intracutaneously administered "produced slightly less response."

Perry⁹ (1937) employed a course of T.A.B. vaccine consisting of 3 intracutaneous doses (0.05, 0.1, and 0.1 ml.) administered at weekly intervals; and, for the control group, subcutaneous doses of 0.5, 0.8, and 1.0 ml. He stated that these procedures were equally effective in the production of "H" and "O" agglutinins.

Wyandt, Bayliss, Tollman, and Gunderson¹⁰ (1938) used intracutaneous doses of 0.05, 0.1, and 0.1 ml., and subcutaneous doses of 0.5, 1.0, and 1.0 ml. of T.A.B. vaccine. In both courses of vaccination, the doses were spaced by 1 week. These workers reported that the subcutaneous course produced approximately twice the antibody [agglutinin] response of that produced by the intracutaneous doses.

Van Gelder and Fisher¹¹ (1941) reported on a large group of children in whom they found an equal degree of response to "H" antigens by the intracutaneous and subcutaneous methods, but the latter produced a higher average "O" titer. Despite the inferior production of "O" agglutinins produced by the intracutaneous doses of 0.05, 0.1, and 0.15 ml., these workers recom-

mended this course for subjects weighing 120 lb. or more, in preference to the usual dosage administered subcutaneously.

Naimer and Nerb¹² (1943) vaccinated respective groups of children intracutaneously (0.1, 0.2, 0.3, and 0.4 ml.) and subcutaneously (0.5, 0.75, and 1.0 ml.). They reported that "The intracutaneous injections were followed by a slightly higher ["H" and "O"] titer formation although the difference is hardly significant."

Leibovitz¹³ (1943) reported that higher "H" and "O" titers were produced in girls vaccinated intracutaneously with 0.05, 0.1, and 0.1 ml. of T.A.B. vaccine, than in boys vaccinated subcutaneously with ten times this dosage; and that "O" agglutinins disappeared more rapidly from the blood serum of the subcutaneously vaccinated boys during a period of 13 months, implying that intracutaneous vaccination favored persistence of "O" agglutinins.

Kamp¹⁴ (1943) vaccinated a total of 946 children with an intradermal course of 0.1, 0.15, and 0.2 ml. of T.A.B. vaccine, and concluded, on the basis of previous work and on his own findings of economy and marked absence of general reactions, and a minimum of discomfort associated with the local reactions, that "Sufficient work has been done to warrant using this method as a means of initial typhoid fever immunization."

Thus, it will be seen that the production of agglutinins has been quite generally accepted as an index to the production of protective substances, or as a criterion for appraising the relative effectiveness of intracutaneous and subcutaneous vaccination. This paper reports a direct determination of protective antibodies, as demonstrated by mouse protection tests, produced by each of the two methods of immunization under discussion; and a comparative evaluation of these methods on the

basis of demonstrable protective substances in the blood serum. Typhoid "H" and "O" agglutinative titers have also been determined as a matter of interest only.

THE PRESENT INVESTIGATION

Subjects—These were medical students, first and second year, recruited from six major universities. Only those students whose histories were negative for typhoid fever and for antityphoid vaccination were included in this study.

The Vaccine—Triple typhoid (T.A.B.) vaccine¹⁸ prepared in the Division of Biologic Products of the Army Medical School was used exclusively.

Dosages of Vaccine—A review of the literature, and of unpublished work brought to the author's attention by advocates of the intradermal method, indicate that three courses of vaccine have chiefly been used and recommended for intracutaneous vaccination: (a) 0.05, 0.1, and 0.1 ml., (b) 0.1, 0.15, and 0.2 ml., and (c) 0.1, 0.2, and 0.2 ml. It appears that 0.2 ml. represents the maximum amount of material that can be injected intracutaneously without producing undue physical destruction of tissue, or leakage into subcutaneous tissues. To those individuals in the control groups, the standard course (0.5, 1.0, and 1.0 ml.) of vaccine was administered subcutaneously. The interval between doses was, in all instances, 7 days.

Collection of Serum—All subjects were bled from 1 to 7 days prior to the administration of the first dose of vaccine, and again 14 days following the last dose. The serum was separated aseptically, and stored in the refrigerator without the addition of a preservative.

Instructions to Group Leaders at Medical Schools—In order to standardize the procedures as nearly as practicable at the six medical schools participating in this investigation, the following instructions (altered slightly)

were circularized among the group leaders:

"This comparison of the immunogenic effectiveness of intracutaneous and subcutaneous administration of triple typhoid vaccine will be based on the results of serum protection tests. However, both 'H' and 'O' agglutinative titers of the sera will also be determined. It is requested that the following outlined procedures be adhered to as closely as practicable in order that this and similarly treated groups may be considered jointly as one large group.

"1. Only primary cases should be chosen. Histories of previous antityphoid immunization and of typhoid and paratyphoid fevers should be negative. . . .

"2. Groups (classes) should be divided, as nearly as possible, into two subgroups of equal numbers—one to receive vaccine intracutaneously, the other to be vaccinated subcutaneously.

"3. Triple typhoid vaccine, prepared at the Army Medical School, will be used. This is the stock 'Army T.A.B.' product, and will be supplied in adequate amounts.

"4. Recommended Dosage: Intracutaneously, one of the following: (a) 0.05 cc., 0.1 cc., and 0.1 cc., (b) 0.1 cc., 0.15 cc., and 0.2 cc., (c) 0.1 cc., 0.2 cc., and 0.2 cc. Subcutaneously, 0.5 cc., 1.0 cc., and 1.0 cc. In each instance, the interval between doses should be one week.

"6. Specimens of Serum: A 30 cc. specimen of blood should be drawn from each person just prior to the administration of the first dose of vaccine, and again on the 14th day following the last dose. The serum should be aseptically separated and bottled (or tubed), and plainly labeled with the person's name and the date on which the specimen was collected . . ."

PROTECTIVE TITERS

Serum protection tests⁴ were performed on all sera to determine the extent of production of typhoid protective substances, but protective titers for *Salmonella paratyphi* and *Salmonella*

schottmuelleri were determined on only a limited number of sera. Typhoid protective titers have been recorded in Tables 2 and 3, and summarized in Table 4. Since the disparity between the two intracutaneous courses consisting of the larger doses is not significant (0.05 ml.), the titers of individuals receiving these courses have been combined in Table 3. Para A and B protective titers have been recorded in Tables 5 and 6 respectively.

AGGLUTININATIVE TITERS

Typhoid "H" and "O" agglutininative titers were determined by the familiar test-tube titration method with standard "H" (formalinized H-901)

and "O" (alcohol-treated O-901) antigens. These titers have been recorded in Tables 7, 8, and 9.

DURATION OF PROTECTIVE AND AGGLUTININATIVE ANTIBODIES

Leibovitz¹³ reported a more substantial duration of agglutinins in intracutaneously inoculated children than in their subcutaneously vaccinated controls. In view of this finding, it was thought desirable to study this factor of duration in respect to protective substances before concluding our investigation. Sera from the participants of the original vaccination experiment who were still available and eligible* for follow-up tests were obtained through the coöperation of group leaders at three of the participating medical schools. However, a total of only 18

sera representative of each vaccinated group were received. These were titrated for agglutinative and protective antibodies for whatever information they would provide. Results of these titrations have been recorded in Tables 10 and 11.

REACTIONS

Data on reactions were collected by a method somewhat different from any that has hitherto been used. At the time of administering the first dose of vaccine, each student was given a blank form (illustrated below) on which he was requested to record his reactions. Instructions to group leaders who supervised the procedures at their respective schools read as follows:

"Reactions: These should be recorded by the individuals themselves, in their own words and with a minimum of coaching or warning of manifestations to be anticipated. The attached form, copies of which will be supplied, is suggested for the use of each individual."

* Some of the participants had been inducted into the Army or Navy and revaccinated before the expiration of one year.

This method is admittedly not without its faults, but it does possess certain advantages: Although it stimulates an anticipation of some ensuing reaction, there is an absence of suggestion of specific manifestations; a convenient

form is available for recording the reactions at or soon after the time they occur, so that there are no blanks nor vagaries due to lapse of memory; and the records are made in a uniform manner, thus facilitating tabulation of data.

TABLE 12

Summary of Local and Systemic Reactions Following Subcutaneous Injections of the Standard Dosage (0.5, 1.0, and 1.0 ml.) and Intracutaneous Injections of One-tenth to One-fifth of this Dosage (115 Persons in Each Group)

It is believed that these students were sufficiently advanced and trained to observe intelligently and record accurately the simple manifestations likely to be evoked by T.A.B. vaccination.

A summary of the individual reports received from the students has been entered in Table 12. There was one minor alteration: remarks such as "drowsiness," "felt tired," "muscular weakness," "not hungry," "faint feeling," "sluggishness," and others having similar implications, were grouped under the general heading of *lassitude*. When entries under the 24 hour and 48 hour periods differed, that entry indicating the more severe reaction was chosen for inclusion in the tabulated data.

DISCUSSION

Protective Titers—It appears that the intracutaneous course of 0.05, 0.1, and 0.1 ml. of T.A.B. vaccine is not as effective in the production of typhoid, paratyphoid A, and paratyphoid B protective substances as is the course consisting of 0.1, 0.2, and 0.2 ml.; also, that the latter is, in general, not as effective in respect to protective titers as is the standard subcutaneous course of 0.5, 1.0, and 1.0 ml. of vaccine. It is true that the differences in the latter comparison do not loom up as widely separated values, but it is believed that they are significant in view of the constant tendency in each of the six groups to favor the standard subcutaneous course.

Agglutinative Titers—As stated earlier in this paper, typhoid agglutinative titers were included only as a matter of interest. The "H" and "O" titers produced by the standard subcutaneous vaccination were, in general, higher than were those produced by any of the intracutaneous courses.

Duration of Protective and Agglutinative Antibodies—Unfortunately, we are dealing with too insignificant numbers of subjects to arrive at any definite

conclusions. Leibovitz¹³ vaccinated 41 girls (average age 10) intracutaneously with 0.05, 0.1, and 0.1 ml. of Lederle's T.A.B. vaccine, and 44 boys (average age 10) with a subcutaneous course of 0.5, 1.0, and 1.0 ml. of the same vaccine. He reported that the greater percentage of subjects with the higher "O" agglutinative titers were in the group vaccinated intradermally, on determinations made 13 months after vaccination, using the rapid slide agglutination technic of Welch and Stuart.¹⁹

We, on the other hand, vaccinated 18 young adult males intracutaneously with a course of 0.05, 0.1, and 0.1 ml. (or more) of Army T.A.B. vaccine, and a comparable group of persons subcutaneously with 0.5, 1.0, and 1.0 ml. of the same vaccine. At the end of 1 year, we found that both agglutinative and protective titers were higher, on an average, in the subcutaneously vaccinated individuals. Our agglutinative titers were determined by means of the commonly used tube titration method.

In summation, there was no suggestion in our results that these antibodies persisted longer in the blood serum of intracutaneously vaccinated persons than they did in persons vaccinated subcutaneously. Considering the fact that the titers for both types of antibodies were initially (14 days) higher in those individuals comprising the subcutaneous group, there was neither any evidence that persistence of antibodies is a special attribute of the subcutaneous administration of T.A.B. vaccine.

Reactions—A casual inspection of Table 12 reveals that, in general, both local and systemic reactions were appreciably less frequent and severe following intracutaneous injections of vaccine. This is in agreement with all reported studies cited elsewhere in this paper.

However, it was interesting to observe disparities between reactions among some of these vaccinated groups. At one school, for example, lymphadenitis

was much more frequent and pronounced among intracutaneously vaccinated individuals than among their subcutaneously vaccinated controls. At a different school, another irregularity noted was the almost indistinguishable rate of frequency and degree of severity of systemic reactions among intracutaneously and subcutaneously vaccinated persons. In fact, the third dose was not given to two persons in the intracutaneous group because of the severity of reactions, described as (1) "Very ill, chills, fever 104°," and (2) "Severe rash (Hives) with confluent wheals." At this same school, the third dose was also omitted in the case of one person in the subcutaneous group because of "Hives over entire body, swollen face, temp. 102°." In each instance, these reactions were reported to have occurred within 24 hours following the administration of the second dose of vaccine. The group leader at this school, in commenting upon reactions, remarked that he was "rather surprised at the slight difference between the groups." In general, however, there is little doubt of the relatively fewer and milder reactions evoked by the intracutaneous injections of the small doses of T.A.B. vaccine employed in this investigation.

Although we have not had an opportunity to observe late granulomatous reactions following intracutaneous injection of vaccine in individuals comprising this study, we have noted chronic granulomas in other intracutaneously inoculated persons. Tilden and Arnold¹⁵ have reported their observations of this late reaction in the Hawaiian population reported by Fennel⁵ to have been vaccinated chiefly by the intradermal method.

In the full awareness of the occurrence of occasional undesirable symptoms attributable to the subcutaneous dosage of T.A.B. vaccine, it is thought that too much weight has probably been given to reactions as a criterion

for appraising methods of vaccination. While it is unquestionably desirable that reactions be reduced in frequency and severity (if this reduction can be accomplished without a reduction of immunological response), we do not agree with Van Gelder and Fisher¹¹ who stated: "It is this difference in reactions that renders the intradermal method superior to the subcutaneous method for typhoid immunization." After all, these are *immunizing* procedures; and, since neither is dangerous to life or injurious to health, superiority of one method over another must be based upon the degree of *immunological response*, not on the degree of freedom from annoyance.

Other Observations—The value of a combination of six group studies conducted according to a uniform set of stipulations, rather than the study of a single group, was made apparent in many ways. As an example, assuming that only the one school cited above (whose intracutaneously and subcutaneously vaccinated groups manifested almost the same rates and degrees of systemic reactions) had been observed, the relative innocuousness of intradermal injection of T.A.B. vaccine, quite evident in the other five schools, would not have been confirmed. In another instance, the protective titers produced by the two methods of administering vaccine, although slightly in favor of the subcutaneous method, were not significantly so as they were in the other five comparative groups. In still another instance, typhoid "H" and "O" titers were so nearly equal that, from this single comparison one would be forced to conclude that the two routes and the dosages employed were equally productive of agglutinin titers. In short, if it were not for the five other comparative groups acting as a counterbalance on some one observation made of a single group, it is easy to discern at least three conclusions that

would be divergent from those that have been set forth below.

CONCLUSIONS

1. The standard subcutaneous course of T.A.B. vaccine consisting of 0.5, 1.0, and 1.0 ml., is more effective in the production of typhoid, paratyphoid A, and paratyphoid B protective substances than is one-tenth to one-fifth of this dosage intracutaneously administered.

2. The standard subcutaneous course of T.A.B. vaccine is more effective in the production of typhoid "H" and "O" agglutinins than is one-tenth to one-fifth of this dosage intracutaneously administered.

3. In small experimental groups, there was found no evidence that persistence of agglutinative or protective antibodies, at the end of 1 year, is a special attribute of either intracutaneous or subcutaneous administration of T.A.B. vaccine.

4. Although local and systemic reactions are more frequent and pronounced following administration of the standard subcutaneous doses of T.A.B. vaccine than following the intracutaneous injection of one-tenth or one-fifth of these doses, it is not felt that we can risk any lowering of protection for the questionable reward of milder reactions. Under the best of conditions of immunological response to artificial immunization, we cannot expect our standard method of vaccination to be adequate at all times in the field to the challenge of infecting organisms. Adoption of the intracutaneous administration of reduced doses of T.A.B. vaccine would seem to increase this inadequacy.

5. It is not to be inferred from these conclusions that the intracutaneous administration of T.A.B. vaccine for the establishment of initial immunity is indiscriminately condemned. On the contrary, intracutaneous vaccination has a definite usefulness in its application to elderly persons and to allergic individuals, in whom severe or serious disturbances may be avoided by the administration of reduced doses, intradermally placed.

6. It is neither to be inferred that we consider the standard subcutaneous course of T.A.B. vaccination as the ultimate in anti-typhoid vaccination procedures. Intervals between doses, and the doses themselves, would bear investigation. Preliminary studies on these questions are now in progress.

ACKNOWLEDGMENTS: The author gratefully acknowledges the help and coöperation of a number of contributors who have, by bleeding and vaccinating their groups of subjects, provided the bulk of material required for this study. Among these contributors are Dr. John F. Kessel of the University of Southern California, Drs. Stuart Mudd and

Harry E. Morton of the University of Pennsylvania, Dr. Theodor Rosebury of Columbia University, Dr. Earle H. Spaulding of Temple University, and Dr. Donald S. Martin of Duke University. Our thanks are also due Dr.

Leland W. Parr of George Washington University for securing the coöperation of his medical students. And to the many volunteers whose blood serum made this study possible, we wish to express our sincere appreciation.

Institute on Rural Youth Migration

The Annual Meeting of the Institute on War and Postwar Problems of Rural Youth Migration was recently held in Washington, D. C., including a section on Rural Health Conditions under the Chairmanship of C. L. Williams, Jr., M.D., of the States Relations Division, U. S. Public Health Service. Other members of the section interested in public health included Anna Heisler, R.N., U. S. Public Health Service, Fred Mott, M.D., U. S. Public Health Service and Chief Medical Officer of the Farm Security Administration, and Arthur J. Lesser, M.D., Regional Medical Consultant, U. S. Children's Bureau.

It is reported that there was agreement at the Institute that health and medical services are important contributing factors to community morale. It was realized that such services are distributed among the population with more regard to the ability to pay than

to actual need. It was concluded that the availability of health and medical services in rural areas should be regarded as a right rather than a luxury dependent upon individual or community purchasing power. Specific recommendations included:

(a) The further extension of existing public health services, with special emphasis on the local level, was urged. The system of public health districts developed by the Committee on Administrative Practice of the American Public Health Association and based upon population and area was approved in principle and its acceptance urged.

(b) The further extension of existing medical, dental, and nursing services including hospitals and clinic services was favored. Medical and Hospital facilities should be made available to all people regardless of their place of residence or their financial status. The war has shown a need for more physicians, especially in rural areas. Accordingly, provisions should be made for additional training facilities to meet the war and the anticipated postwar demand for medical care.

Some Factors Affecting the Early Diagnosis of Pulmonary Tuberculosis

Study of 230 Newly Reported Cases

BERWYN F. MATTISON, M.D., M.P.H.

*District State Health Officer, New York State Department of Health,
Kingston, N. Y.*

THE purpose of this investigation was to study some of the factors limiting the efficacy of case finding among symptomatic groups, to note differences in the potential value of contact examinations depending on the type of community, and to emphasize the important rôle of mass surveys of selected population groups in future tuberculosis control programs.

METHOD OF COLLECTING DATA

The exact time at which the patient first became aware of a departure from normal usually cannot be determined from hospital or clinic records. Even less satisfactory is the information from such records regarding history of illness among current or former contacts of the patient, not only with regard to tuberculosis, but concerning any suspicious symptoms referable to the chest. Furthermore, no detailed residence history is usually available, and it was desired to observe the variation of several factors according to a history in the past of residence in an urban versus a rural community.

Therefore, the primary source of the data was personal interview of patients. This was supplemented by reference to hospital, clinic, and public health records. Wherever there was a question of a contact having suspicious symptoms

and there were relevant hospital or other medical records, these too were examined. In each case the family physician was consulted and the individual and family history discussed with him. As the patient interviews were all conducted by one individual, differences due to differing interpretation, approach, etc., were minimized.

The area selected for the study included three counties in upstate New York. Two were predominantly rural, the third included a city of about 200,000 population. In order that these personal interviews would be most productive, and so that the results would mirror as closely as possible the current picture of tuberculosis, the group selected included those cases reported for the first time during the year 1941 and still living in the same area. It will be noted that this was at the beginning of the war before mass radiography became relatively common.

Cases for which there was evidence of a previous report in the district roster were excluded. As the interviews were completed during the 8 months between October 1, 1941, and June 1, 1942, the loss by death of cases reported during 1941 was not high—56 of 353 cases (16 per cent).

It was found that these deceased cases could not be included because the de-

sired data to be used comparatively were not available from existing records. Of 251 patients still living in the area and capable of being interviewed, 230 (91.7 per cent) were located and are included in the investigation.

Each of the three counties has easily accessible chest clinic facilities, and in none was there a shortage of physicians at the time of the study.

The following information was obtained on each patient:

Identifying data—name, address, date of birth, marital status, sex, color, parents' birthplace, occupation, and attending physician.

Apparent onset—date and nature of first symptoms referable to the chest; date and reason for first medical consultation subsequent to these symptoms; first chest x-ray; date, by whom taken, by whom referred, and result; date and source of x-ray on which diagnosis was first made; place, date, and result of sputum examinations; reporting: date, by whom, stage and activity of disease at that time.

Treatment—dates of sanatorium residence or home "curing."

Residence—places of residence from birth to age of 15 years; from 15 to 30 years; and subsequently—with time spent in each place.

Contact history—included all persons with one month or more household association with the patient since the latter's birth; also any known extra-household contact who had been diagnosed tuberculous. Information secured on the former included: name, relation to the patient, address, age, presence of suspicious chest symptoms (at any time), x-ray examination if performed, current status (non-tuberculous, definite tuberculosis, or suspect), date and cause of death if deceased, and dates of contact with the patient.

The data were transferred to punch cards and mechanically sorted.

DIAGNOSIS

In 222 of the 230 cases the diagnosis was established by means of x-ray films; in 4 the original diagnosis was made on the basis of fluoroscopy, and in 3 on sputum examination. In one instance the disease was discovered at the time of an operation.

Over half of the cases (124) were reported by a chest clinic, 48 by a tuberculosis hospital, 48 by a private physician, and 10 by general or other hospitals.

Among the 230 patients there were 30 who had been diagnosed more than a year earlier but not reported as cases until 1941; and another 60 had been aware of symptoms referable to the chest for a period of more than a year before reporting. Thus, nearly 40 per cent of this group of newly reported patients had definite evidence of disease for a considerable period prior to reporting.

VARIOUS FACTORS RELATED TO STAGE OF DISEASE AT REPORTING

1. *Age and sex*—There was a greater proportion of minimal cases reported among females than among males. Table 1 shows that there were 40.7 per cent minimal cases among the former and only 30.3 per cent among the latter. This difference is also reflected in the

TABLE 1
Stage of Disease at Reporting According to Sex of Patients

Sex	All Stages		Tb. Pleurisy		Minimal		Mod. Adv.		Far Adv.		Stage at 1st Report Not Determined	
	No.	Per cent	No.	Per cent	No.	Per cent	No.	Per cent	No.	Per cent	No.	Per cent
Total	230	100	5	2.2	81	35.2	64	27.8	64	27.8	16	7.0
Male	122	100	2	1.6	37	30.3	34	27.9	40	32.8	9	7.4
Female	108	100	3	2.8	44	40.7	30	27.8	24	22.2	7	6.5

proportion of far advanced cases according to sex.

A possible explanation is offered in the observation that more of the symptomatic females consulted a physician within a month of their onset than did symptomatic males. This increased delay on the part of the men in securing medical attention was not limited to any one age group. In the ages 0-29 and over 30 years, the males had 45.2 per cent and 51.7 per cent respectively soliciting medical aid within a month following first symptoms; whereas the females had 65.8 per cent and 64.3 per cent respectively. It seems quite likely that this is a manifestation of the frequently observed tendency among male patients to belittle the importance of all but the most serious symptoms.

2. *Parental nativity*—Foreign population groups are generally considered to present more of a problem in tuberculosis control than other groups, particularly in urban areas. It is not always clear why this should be except where living conditions offer an explanation. Table 2 shows that in this study (where

erative. However, so far as the original discovery of the disease is concerned they were not found to vary notably from the rest of the group: 54.8 per cent of the patients of native parentage sought medical advice within a month of their onsets and 52.2 per cent of patients of foreign parentage.

3. *Residence history*—Because of the long intervals frequently elapsing after tuberculous infection before overt signs of disease appear, not only the patient's whereabouts at the time of diagnosis but also his whole residence history is of interest. Because of the more frequent association between individuals in an urban society, the spread of any respiratory disease there might be expected to assume a different pattern than that in a rural area.

Of the 230 patients studied, 156 had lived for one year or more in a city of 100,000 population or greater; and 57 of the remaining 74 had lived all of their lives in places of 50,000 or less. There was no significant difference in the subjective manifestation of illness in those with and without extensive large

TABLE 2
Stage of Disease at Reporting According to Parental Nativity

Information incomplete	17	100	0	...	1	...	0	...	0	...	16	...

practically all of the patients were native born) the factor of parental nativity was not associated with any significant difference in the stage of disease at reporting.

Because of frequent unwillingness to be hospitalized these first generation natives are often thought to be uncoop-

city experience: Of the 156 patients residing in large cities 85.9 per cent were symptomatic, and of the 74 residing in rural areas 83.8 per cent had symptoms.

But there was observed a very definite difference in regard to the stage of disease at reporting. In the more urban-

ized group there were only 30.8 per cent of minimal cases compared to 47.3 per cent in the more rural group. This seemed surprising in view of the fact that diagnostic facilities were, if anything, more easily available in the urban areas, and lay tuberculosis education probably had been more intensive there. Those patients who had been resident for some time in a rural area before being diagnosed showed a tendency to have more advanced lesions if they had a history of past urban experience.

This difference cannot be explained on the basis of age or sex differences. However, there is a residence-linked characteristic (known prior exposure) which may present an explanation, and which will be considered in the succeeding paragraphs.

4. *History of recognized tuberculosis contact*—Among the patients 139 (60.5 per cent) gave a history of known contact with a previously diagnosed case of tuberculosis. Table 3 shows the

alone, 15 out of 19 (79 per cent) were minimal on discovery. In a larger group (34) who were asymptomatic—regardless of the reason for the examination leading to their diagnosis—28 (82.3 per cent) were minimal.

As might be expected the history of recognized household contact was associated with slightly larger family groups—the 88 patients with such a history naming 685 current or past household associates for an average of 7.8; while 142 patients without such a history named 1,025 for an average of 7.2. Likewise multiple antecedent household contacts were associated with larger families; the median family size where there was no history of contact was six; with 1 recognized contact it was 7; with 2 it was 9; and with 3 it was 11.

In view of the earlier diagnoses among contact groups it is easier to understand the findings noted above regarding the higher proportion of minimal cases in persons of rural residence. For, as is

TABLE 3

Stage of Disease at Reporting According to History of Recognized Antecedent Contact

History of Contact	All Stages		Tb. Pleurisy		Minimal		Mod. Adv.		Far Adv.		Stage at 1st Report Not Determined	
	No.	Per cent	No.	Per cent	No.	Per cent	No.	Per cent	No.	Per cent	No.	Per cent
Total	230	100	5	2.2	81	35.2	64	27.8	64	27.8	16	7.0
Household	88	100	1	1.2	43	51.8	22	26.5	16	19.3	1	1.2

No recognized contact	91	100	3	3.6	29	28.6	28	33.3	29	34.5	0	...

marked relation between antecedent household contact and the early discovery of the disease. This is due no doubt in part to the better understanding of the disease in those persons who have had such direct contact with it. Probably, too, it is largely due to the frequency of contact examination in that group before symptoms appear. This supposition is strengthened by the fact that in a small group of persons examined primarily because of contact

seen in Table 4, 55.4 per cent of the more rural dwellers gave a history of previous household contact with a diagnosed case; and only 30.1 per cent of the urbanized patients gave a history of recognized household contact.

This would seem to be the natural manifestation of the greater hazard of tuberculous infection from unrecognized sources in areas of greater concentration of population. In the less concentrated areas actual physical association between

TABLE 4

History of Recognized Tuberculosis Contact According to Patient's Residence

<i>History of Contact</i>	<i>Total</i>	<i>Residence for One Year or More in a City of 100,000 or Greater</i>		<i>Residence Solely in Smaller Places</i>	
		<i>No.</i>	<i>Per cent</i>	<i>No.</i>	<i>Per cent</i>
Total	230	156	100	74	100
Household	88	47	30.1	41	55.4
Extra household	51	36	23.1	15	20.3
No recognized contact	91	73	46.8	18	24.3

persons is more likely to be focalized in the home, with proportionately less intimate contact between persons outside of their own family circles.

This is of considerable importance from an administrative point of view for it delineates to some extent the differing part that contact investigations should play in the over-all control program in rural and urban areas. Obviously the 70 per cent of urban patients discovered with no known antecedent household contact would not have benefited by a more extensive and complete examination of the household contacts of known cases. To discover them earlier it would have been necessary to have done one of two things: Either secure more prompt action by patient and physician after symptoms developed; or discover them before the

appearance of symptoms by means of mass x-raying other than that of the household contacts of known cases. The first possibility will be considered next.

5. *Delay by the patient*—At one time it was felt that intensive lay education regarding the "symptoms of early tuberculosis" might be the solution to early diagnosis. Undoubtedly the longer a patient delays after symptoms develop before seeking medical attention, the more extensive his lesion will be on diagnosis. Table 5 illustrates this point, 47.8 per cent of the patients being far advanced who delayed more than a month in seeking medical advice, whereas only 28.4 per cent were far advanced who had gone to a doctor within a month of the onset of symptoms.

But other important considerations

TABLE 5

*Stage of Disease at Reporting According to Manner of Onset and Delay in Seeking Medical Attention **

<i>Interval from Onset to Medical Consultation; and Stage of Disease at Reporting</i>	<i>Total</i>		<i>Initial Symptoms</i>

* Excluding 40 patients with no medical consultation and 33 patients diagnosed prior to 1941

are involved. It is apparent that the nature of the first symptoms are very important. In the 83 patients with an insidious onset, even those who sought medical care promptly (37.4 per cent saw a doctor within 1 month) benefited little from their good "reaction time" as but 22.6 per cent were minimal when reported. Even with the more alarming types of onset, early medical consultation (78.2 per cent saw a doctor within 1 month) resulted in but one-third of the patients being diagnosed in the minimal stage.

This does not present a very encouraging picture of the possibilities of early diagnosis among symptomatic patients. In the nature of the disease we must expect a considerable proportion of cases to continue to present a slight cough, weakness, loss of weight, or other equally nonspecific symptoms as the initial manifestation. Even in the presence of adequate lay education as to the

occurrence of such symptoms in tuberculosis, it remains more probable that they will be interpreted at first on the more common basis of a "cold," "sinus trouble," "over-work," etc.

Figure 1 illustrates the time lag in securing medical attention as related to the reporting of the cases after such consultation. It is seen that medical consultation was reasonably prompt, with over 70 per cent of the patients having seen a physician within 2 months after symptoms appeared.

Age alone had little to do with this lag, 56.5 per cent of the symptomatic patients under 30 having seen their doctor within a month and 55.7 per cent of those 30 years or over having done so (See Table 6). However, the young adult males showed a definite tendency to procrastinate longer than females of the same age group.

6. *Delay by the physician*—The diagnosis of early tuberculosis is often ex-

FIGURE 1—Intervals between onset and medical consultation and between onset and reporting for 184 patients with symptoms referable to the chest

No medical consultation	46		23		23	

tremely difficult in practice. It would be expected that a considerable delay might occur in securing a diagnosis in some patients after they sought medical advice. It has been seen (Figure 1) that there was a rather pronounced lag in reporting cases to the health department. This is unfortunate in that it delays the initiation of a concerted attempt to secure hospitalization and to institute control measures in the home.

There was also a considerable delay noted in securing the initial x-ray after first medical consultation. As indicated in Table 7, 67.5 per cent had been so examined within 60 days' time, but after that interval there were 60 patients who did not get an x-ray for months or even years.

The likelihood of long delays in securing the x-ray needed to give a definite diagnosis increased with the age of the patient. There was no observed difference between the sexes in this regard. Table 8 shows that many of the instances of considerable delay occurred in the older age groups. This emphasizes again the relative importance of suspecting the elderly patient with symptoms—the patient with "bronchitis," or "asthma"—on whom an x-ray of the chest should be done routinely at the earliest possible moment.

Time studies of the various lags described have not been frequently reported. Chapman² reported a similar analysis of 200 patients in 1928. It is interesting that at that time he found 61 per cent of his cases had consulted

TABLE 8

*Interval from Medical Consultation to X-ray According to Age at Diagnosis
(Excluding 46 Cases Without Medical Consultation)*

a doctor within 1 month of their first symptoms. In spite of the extensive lay education since that time regarding the symptoms of tuberculosis the proportion of cases in this study who acted that promptly was almost identical (59.8 per cent).

Nicholson⁴ recorded a similar interval for her series in Detroit—again 61 per cent having seen a physician within 1 month of their onset. This is of particular interest in that her study included only fatal cases, and the median interval between diagnosis and death was only 6 months.

More recently Mann³ has reported a similar analysis of the steps leading to a diagnosis of tuberculosis in England. It is not possible to compare his findings with those mentioned above because of different statistical treatment of the material. He did, however, observe the same tendency to increased lags in the older age groups and emphasized the point that much of the delay in instituting early treatment is due to the development of tuberculosis without symptoms or with only "nonspecific" subjective manifestations.

Pope and Chadwick⁵ have recently pointed out the importance of determining the proportion of currently discovered cases associated with antecedent contact with a diagnosed case, as some measure of the value of contact examinations. The difference observed in this study between urban and rural areas suggests again the relatively greater importance of the examination

of household contacts in rural areas, and the greater need of additional case finding procedures besides contact examinations in the cities.

DISCUSSION

Both from the clinical and the public health viewpoint the early diagnosis of tuberculosis is extremely important. Except for differences in inherent resistance, the prognosis depends largely on the stage of disease at which treatment is instituted. Even if an effective drug is discovered, the degree of pulmonary damage prior to its use in any individual case will undoubtedly determine the period and extent of disability.

Similarly the community suffers an infection hazard from each case which is proportionate to the interval between beginning infectiousness and institution of proper control measures. This interval is a function of the promptness of diagnosis wherever adequate facilities for the treatment, segregation, and education of discovered cases are available and properly utilized.

Furthermore, lay coöperation in any control program is likely to be conditioned by the experience of laymen regarding the measures advised. And when the majority of tuberculous patients are diagnosed in an advanced stage, popular conceptions of the efficacy of sanatorium care are formed on the basis of the discouraging results observed in treating those late cases. Only when it is usual for tuberculosis to be diagnosed early will the dread of sana-

toria disappear and a confidence in current treatment methods become common.

Part of the unsatisfactory results of our older control measures was attributable to the insidious nature of the disease. For many years the chief emphasis in lay education was on symptoms, and our principal professional implements were physician education and consultation clinics for patients with complaints referable to the chest. These measures were obviously incomplete in view of statements by eminent chest specialists that as high as 60 to 70 per cent of patients have advanced lesions by the time they are aware of their illness.¹

It is important to consider carefully what portion of a tuberculosis control program should be based upon the symptomatic patient and what portion on an aggressive case finding effort aimed at people who are not yet ill. Each requires specific administrative, clinical and technical personnel and equipment peculiar to its own needs.

The "reaction time" of the patient with symptoms in soliciting medical aid must affect in some degree the stage at which his disease is discovered. This particular lag has been measured in the past² before the laity was as well informed as it is today. Yet the lag has not changed appreciably when compared to that observed in this study and by other more recent investigators.³ It is a moot point as to how much the yield of early cases from symptomatic patients might be increased by more intensive work with these ill persons.

During the past few years, and especially since the outbreak of the war, we have gone on the offensive against tuberculosis, no longer waiting for it to make itself apparent before going into action against it, but searching it out where we know it has not yet become firmly entrenched. A beginning was made in this direction with attempts to x-ray all household contacts of re-

ported cases. Though mostly without symptoms, this group has yielded good returns both of total cases and of early cases. More recently this has been supplemented by extensive examinations of other asymptomatic groups—selective service inductees, industrial workers, low income and colored groups, etc. The development of fluorography and paper film methods has made the future extension of such mass surveys feasible and economical.

The provision of diagnostic services for patients with chest ailments must remain one of our basic needs in controlling tuberculosis. But in order to increase substantially the proportion of early cases diagnosed, more is needed than an increased effectiveness of the handling of symptomatic patients. In this group, even when both patient and physician acted promptly after symptoms appeared, less than half of the cases were minimal when reported.

The proportion of minimal lesions discovered among patients examined for reasons other than symptoms was very considerably higher. The use of mass chest x-ray surveys of selected population groups would seem to be the method of choice in securing earlier diagnosis which in turn should affect all phases of tuberculosis control activities through the greater efficacy of treatment in patients with less extensive pulmonary damage.

SUMMARY

Two hundred and thirty recently reported cases of pulmonary tuberculosis and their household contacts were investigated. In addition to the information routinely available from clinic and hospital records, the patients were questioned in detail as to the reasons for their first medical consultation.

The time lags were determined between appearance of symptoms and seeking medical care; between the first visit to a physician (for symptoms refer-

able to the chest) and the initial x-ray; between that x-ray and a definite diagnosis of tuberculosis; and between that diagnosis and reporting of the case to the health department.

The observations recorded indicate that case finding among symptomatic patients cannot be expected to result in a majority of those patients being discovered at a minimal stage; and contact examination among associates of diagnosed patients, although yielding a high

proportion of early cases, is limited in its scope, especially among urban residents. Mass roentgenography would appear to be needed if substantial reduction of cases which are advanced at the time of discovery is to be achieved.

Rapid Treatment For Gonorrhea With Penicillin

Rapid and simplified methods for treating gonorrhea with penicillin which require no hospital care for the patient and which can be used conveniently by physicians in private practice or by clinics were recently reported by physicians of the U. S. Public Health Service, Washington, in connection with the Service's responsibility for treatment of men from the Coast Guard and Merchant Marine. One schedule of five treatments can be completed in 7½ hours.

Patients are required to be at the clinic for only a few minutes at

each of the five or six times designated for penicillin injections. These rapid treatment schedules were developed because of the urgency of returning men to active duty. According to these reports, the new methods have been effective in almost as large a percentage of cases as the standard 12 to 21 hour treatment schedules. These so-called out-patient schedules of treatment were developed by Drs. C. J. Van Slyke of the Venereal Disease Research Laboratory, Staten Island, N. Y., and S. Steinberg of the U. S. Marine Hospital, New York, N. Y.

Merit System in Public Health

L. E. BURNEY, SENIOR SURGEON, AND F. M. HEMPHILL,
P. A. SANITARIAN (R), F.A.P.H.A.

U. S. Public Health Service, Washington, D. C.

PRESIDENT Garfield was assassinated by a disappointed office seeker. His death resulted in the birth of the Federal Civil Service Act in 1883. Provisions of this Act were well conceived. They have guided states and cities in the formulation of their civil service legislation.

A merit system as generally understood is a civil service without benefit of legislation. Authorization for its development is based upon regulation and not law. Their objectives are the same. Briefly stated, these are: (1) selection of personnel by open competitive examinations admission to which is based upon qualifications and experience; (2) provision of promotions and increased compensation based upon proven ability and length of service; and (3) elimination of partisan politics in the selection, appointment and promotion of personnel.

Representative Fulbright of Arkansas made the following pertinent remarks¹:

"Most of the faults in government can be traced to personnel. Business, because it is profitable, has attracted the smartest people. If you can have a good government—a reasonable, honest and clean government with intelligent people in it—other problems will solve themselves."

It is our desire to present to the public health worker information about the merit system; what it is, how it works, its advantages to the individual and to the public, and finally to list the progress that has been made up to the present time. Our experience leads us

to believe that many persons in public health have not been well informed about this program. Their complete understanding and intelligent support are vital for the development of a successful merit system.

Public health leaders have long appreciated the need for making public health positions more attractive in order to secure and retain qualified and experienced workers. Several of the foundations, notably Rockefeller, Kellogg, and Commonwealth, have done much to stimulate improvements in public health organizations and to encourage graduate training of professional workers in public health. These foundations together with the U. S. Public Health Service and the American Public Health Association have shown that capable personnel are essential to provide efficient, economical public health services to American communities. It was demonstrated that the death rate from typhoid fever in any community could be maintained at zero; that children need never die of diphtheria; that no community need have an outbreak of smallpox; that milk safe for human consumption could be produced; that public water supplies could be developed which would not carry contamination into homes; and, in general, that an extremely low death rate from communicable diseases in any community is very largely a purchasable commodity, provided that trained and efficient public health personnel are employed and are not hamstrung by vested interests.

These demonstrations were well known to the state health officers at the time of passage of the Social Security Act of 1935. Title VI of this Act gave authority for the appropriation of funds to be administered by the Public Health Service (through the state health authorities) for the purpose of assisting state and local public health agencies in developing and expanding such health services, and in providing funds to be used for training personnel. These funds are allotted to the states by the Public Health Service and have given decided impetus to the development of state and local health departments manned by full-time qualified personnel.

Since 1936, the state health officers have invested annually more than one million dollars of these funds in training personnel. There has accrued a valuable backlog of investment in trained personnel. Our American armed forces have drawn heavily on this supply of trained specialists to insure the protection of the health of our fighting forces. The states are maintaining their training programs to a considerable extent even during the war period.

Expenditure of such large sums annually for this necessary and worthwhile purpose receives full support and encouragement from the Public Health Service and the Children's Bureau. These agencies, being charged with responsibility for administering federal funds through states for public health improvement are vitally interested in the careful selection of trainees and in the establishment of adequate standards for their employment in public health work following training.

After such sums of money have been spent on these individuals to insure their greater effectiveness, it is true economy and efficiency to encourage their retention in public health work by providing: an equitable compensation plan, opportunities for advancement

based upon qualifications of training, experience and ability; and last but not least, freeing employment from partisan politics, personal favors, and family ties.

Amendments to the Social Security Act passed in 1939 by The Congress provided that states submit plans for personnel administration on a merit basis to certain federal agencies administering funds made available by the Act. Those agencies which were not included in these amendments, wrote into their administrative regulations a requirement similar to that imposed on the other agencies by Congressional Act. Thus, administrative plans for the funds made available to state and local governments for Social Security programs, including public health, require that state and local units of government employ personnel and administer the activities of personnel under a merit system which is acceptable to the federal administrative agency.

Regulations and policies of the U. S. Public Health Service for the administration of funds through grants-in-aid to the states include certain standards for state plans of personnel administration. These policies and regulations are established by the Surgeon General of the U. S. Public Health Service after consideration and approval by the Conference of State and Territorial Health Officers. The Public Health Service reviews plans for personnel administration as they affect public health personnel in the states.

In addition to the responsibilities placed directly on the Public Health Service by Congressional Acts, there are certain relationships with other federal agencies which often involve the Public Health Service. The Social Security Board of the Federal Security Agency also has certain responsibilities conferred by The Congress in regard to personnel within the states. Under varying types of organization the re-

sponsibilities placed on the Board and the Public Health Service are in some states administered through the same department. It is therefore desirable that the basic policies and regulations of these two agencies be uniform.

The Children's Bureau of the U. S. Department of Labor also shares this responsibility and participates in all state health programs. These three federal agencies make every effort to develop uniform standards for recommendation to the states. Harmonious agreement and clearance in regard to policies of personnel administration in state plans have been developed.

In addition the Hatch Act places certain responsibilities on federal agencies administering grant-in-aid funds.

Progress in state programs of personnel administration for public health employees is divided into three parts: (1) merit system rules including State Civil Service laws; (2) classification, compensation schedules, and (3) operating procedures.

Proposed rules for merit system organization (including 20 states with Civil Service laws which encompass health department employees) have been prepared by each of the states. Provision is made for a council or board which is responsible for policies and guidance. An executive officer of the Merit System program is required by rule or law and his duties and jurisdictions are specified. Agency personnel officers and their duties are given. Among other provisions included in these rules are: (1) method of selection of council and supervisor; (2) selection of personnel by examination; (3) procedures for various types of appointments, leaves, separations, disciplinary actions, reinstatements, appeals, and other personnel actions; (4) general characteristics of the classification-compensations schedules; (5) procedures of payroll certification.

True to the democratic organization

of our states these rules differ in their content in accordance with various state laws and regulations and the circumstances which prevail in the respective states. Throughout, however, the plans and regulations conform in general to sound principles of public personnel administration. Rules and laws of 42 states have been accepted as being in substantial conformity with the Merit System policies of the Public Health Service as of July 1, 1944. States have met more difficulty in developing classification-compensation plans than in formulation of rules and laws. Analyses of positions, required preparation through training and experience for these positions and the establishment of equitable rates of pay have been stumbling blocks. Gradually the states are making progress in solving these problems, but at present only 14 of the states have submitted plans which conform to the standards of the Public Health Service.

Much profitable effort has been expended by the states in preparation of classification-compensation plans based on job descriptions, degree of responsibility in the position, degree of hazard to the employee, etc. This process has led to more basic alignment of positions within departments, consideration and reconsideration of requirements for professional and sub-professional positions, optimum ratios of professional to sub-professional personnel in the various public health activities, adjustment of salaries toward equity of pay for equal work, responsibility and hazard of employment and utilization of compensation schedules in budget planning. Past personnel practices have been carefully scrutinized by many public health administrators and progressive steps made by salvaging the better of these and instituting more desirable practices in lieu of those practices found undesirable. Adoption of well considered compensation-classification schedules by state

and local health authorities have proved to be economical per unit of service rendered; have produced a stable base for future personnel actions; have stimulated individual employees toward self-improvement; and have enhanced the security and stability of the group. Timely adjustments of classification-compensation schedules have gone far toward alleviating stresses of personnel shortage precipitated by the national emergency. States having the more progressive plans and more adequate installations of personnel administration have tended to suffer less from personnel shortage during the emergency although each state has made great contribution in specialized personnel to the military services and to war industry during this period.

Advantages in the field of public health work which experience has shown to accrue from a sound merit system program include:

1. A uniform, publicly-known procedure through which competent qualified personnel may be employed. All recruitment is difficult in wartime. Part of the difficulty lies in the reluctance to assign to auxiliary personnel tasks which formerly were done by professional classes. Probably the largest obstacle is the inability or unwillingness to compete with industry and private enterprise in financial compensation for the services rendered. We are fettered by tradition and custom in paying low salaries to public health workers. Also, many additional responsibilities have been placed upon public health departments demanding new and additional services. There is nothing in a sound state merit system which increases recruitment difficulties that have not been placed there by the agency responsible and which cannot be removed. Realistic revisions of merit system plans have been offered by many state health authorities. These have been welcomed by the Public Health Service and re-

ferred to other states for consideration. States have been urged to include in their merit system classification plans on "emergency class" for the duration of the emergency or until personnel qualified for standard classes become available. Modified duties and responsibilities, with sub-standard qualifications, are proposed for such positions. As an example, the standard class specification may call for graduation of the nurse from a hospital having at least 100 daily bed patient average. During the emergency, however, nurses from smaller hospitals can be taken to perform less responsible work under more immediate supervision. It is reasonable to suppose that there will be some respite from the dearth of professional personnel shortly following the war, but the potential problems necessitate leadership and masterful planning on the part of public health administrators, those who train public health specialists, and the personnel officers of state and local health departments.

2. A procedure for the training of persons for a career service in public health.

3. Establishment, as a basis for personnel selection, of qualifications and experience necessary for particular positions.

The American Public Health Association, through the Subcommittee on Merit Systems of the Committee on Professional Education, has performed an excellent service, both in stimulating interest in the development of merit system programs and in providing test items to be used in the examination of persons in the several specialties. Items are suggested by qualified persons in the field. These are reviewed, edited, and made available to the states.

Sixty-five examinations in the field of public health nursing have been given in 15 states and 1 city. Examination material has been prepared in the field of public health nursing, nurse-mid-

wifery, and orthopedic nursing. Test items are also available for administrative health officers, laboratory programs, and environmental sanitation.

4. Standardized compensation schedules for positions demanding comparable qualifications and pay increases based on efficiency and length of service.

5. Provision of more economical and efficient public service through the employment of competent and qualified personnel who are motivated by a desire to render service rather than to seek special favors.

6. Plans on which retirement benefits may be based.

7. Protection for the public health worker from influences resulting from political changes, from the whims of administrators, and the elimination of at least some of the confusion which may accompany a change in state or local political power. On the other hand, methods are provided for the administrator to discharge employees who do not develop and progress as normally expected. But the employee is discharged for cause, with a public hearing if requested. Meriam² states that "in the national government, the truth is that it is easier to fire a classified civil service employee than it is to fire the employee who holds office by virtue of live, current political connections."

8. Reduction of effect of pressure groups on personnel administration, allowing the administrator more time for his work in public health.

When the personnel of state and local health departments enjoy a reasonable degree of security, and when plans have been put into operation and are known to the personnel for whom they are prepared and to the educational institutions preparing those who would choose careers in the specialties of public health, then considerable progress will have been made. At present there

is much to be desired in the actual operations of the states' personnel administration programs. These operations take time to institute even when there is the best intent on the part of administrators. Experience in working with state and local public health administrators indicates that problems of personnel are and have always been the most persistent and most important. This was true before the emergency as well as now. Personnel selection, retention, and general improvement in standards of employment will be one of the major problems of public administrators after this emergency. Some public health administrators show little desire to develop progressive plans for personnel administration. There are a few who openly prefer political partisan practices including selection and retention of officers and others charged with protecting the health of the public on the bases of friendship, personal favors, and family ties, rather than qualifications of ability, training, and experience. Fortunately few of the latter type administrators become interested in public health services.

Petty politics have proved of little assistance in offering protection against diphtheria, typhoid fever, in the reduction of incidence of venereal disease, or in the solution of other public health problems. Full-time qualified public health personnel have proved quite efficient in reducing disease incidence and in raising the health level of communities. Continued public health progress in the United States depends materially on the quality of service rendered by state and local health department personnel. Provisions for equity of pay for equal work, recognition of responsibility involved, and hazard of the work of the employee will contribute to the elimination of disease hazards. Other phases of sound personnel administration, too, must be utilized in order that qualified persons

may be selected and retained to render service over continuing periods of time—that there may be incentive to study and progress as a public health worker—there may be reasonable security for the meritorious worker—the “dead wood” of health departments may be systematically eliminated.

Basic plans for such procedures have been laid. Their fulfillment rests in the hands of administrators. The blue print is ready—construction of fully effective programs has yet to be accomplished in most states.

Problems of personnel administration are never static. Following World War I a series of problems were presented; the depression period brought entirely different problems with a lush and overabundant labor market; whereas, our present emergency period has produced a great shortage of labor. What the nature of personnel supply will be following this war period is pure conjecture, but it seems reasonable to suppose that state and local health departments will not be able to secure for some time thereafter an adequate supply of trained public health workers. If this proves to be the case, planning for training of personnel will be essential. Plans should be completed for determining how those who have been in the military services of the nation and those who return from essential war industries may be included in public health programs. If industry expands in the post-war period and continues to demand the entire labor supply, public health agencies may continue to have need for aggressive personnel policies.

CONCLUSION

It has been stated: “The health officer occupies the position of agent to whom the public entrusts certain of its resources in public money and cooperation to be so invested that they may

yield the best returns in health.”³ If this be true, the health officer must have a system by which capable personnel can be selected and retained in order that he may fulfil his obligations to the community in the protection and promotion of its health. Personnel determine the success or failure of any organization, private or public.

A merit system provides a means of attracting and retaining qualified and experienced individuals. This is accomplished by open competitive examinations, selection on basis of merit, promotions to those demonstrating initiative and ability plus length of service, and finally compensation commensurate with the responsibility of the position. Concisely, a merit system for public health departments provides a career service in place of the haphazard type of personnel administration now commonly, of necessity, employed.

The advantages of a merit system are many, both to the public and to the employees. Taxpayers' returns in health can be best achieved by full-time well qualified professional personnel selected on the basis of merit and experience through well administered, competitive examination.

Sound personnel administration within state and local health departments is a responsibility of the state and local administrative health officers.

The strength of America is its man power. Disease is man's worst enemy. The employment of inefficient, dissatisfied personnel hamstrung by vested interests and by penny-wise dollar-foolish budgets amounts to sabotage in any community's war against disease.

Popular Health Education

ARTHUR MASSEY, C.B.E., M.D.*

Medical Officer of Health, Coventry, England

NO matter what the authorities do on behalf of the public health, their measures will fall short of maximum success unless the individuals of the community accord ready and intelligent coöperation. To this extent it can be said that the individual himself is often the final arbiter in regard to his state of health. It is thus of first importance to interest the public in medical measures and to teach them self-help in health matters. It is to these ends that popular health education is practised.

The commercial publicist indicates to us many principles worth emulating, such as continuity of effort, novelty of presentation, and the objective approach.

The health publicist enjoys advantages, for it is certain that the people want what he is out to offer them. Then there is the point that, whereas the commercial advertiser has to face competition, health educators are all, as it were, advertising the same commodity.

Although an analogy with commercial practice is helpful, it is to be emphasized that health education comes essentially within the professional sphere and must retain a scientific basis.

ENGLISH PRACTICE

The Ministry of Health takes the initiative centrally in regard to popular

health education, and in wartime works in complementary fashion with the Ministry of Information in this matter. In practice much is delegated to a body known as the Central Council for Health Education acting as agent for the Ministry of Health in this connection. The Central Council is widely representative, and among the bodies that nominate members to it are the Ministry of Health, the Board of Education, the Society of Medical Officers of Health, the British Medical Association, and various associations of local authorities.

In the past there has been a large number of separate voluntary bodies each dealing with some limited aspect of health education. Many of these still exist; but the tendency is to rationalize the position and to widen the scope of the Central Council.

During the war, the Ministries of Health and Information and the Central Council have increased notably the output of health propaganda. In these activities they work as far as possible through the well tested machinery of the local authorities and their public health departments.

The wartime posters produced centrally have reached a consistently high standard. No instance of this is more striking than the series of posters designed to illustrate the slogan "Coughs and Sneezes Spread Diseases." The primary injunction is to make proper use of the handkerchief in order "to trap the germs."

Antivenereal disease propaganda, in

* Guest of the American Public Health Association at the fourteen state and regional meetings during May and June, 1944.

the form of posters, articles, and advertisements in the national newspapers and journals, has also been persistent and striking. Some measure of its effectiveness is to be found in the marked increase at all venereal disease treatment centers of the persons attending for examination at the centers and found to be "not V.D."

BROADCASTS

From time to time, during the past two years or so the Chief Medical Officer of the Ministry of Health (Sir Wilson Jameson, K.C.B., M.D.,) has talked on the air in convincing fashion on outstanding health topics. His broadcasts on the venereal disease problem and on immunization against diphtheria are classics.

Popular features in the British broadcasting program are the regular talks by the "Radio Doctor." In these talks, everyday health matters are dealt with in a scientific but homely way.

A good medium of health education is also provided by the BBC in the form of discussions—sometimes between experts and sometimes between ordinary folk—on health subjects.

FILMS

In regard to health propaganda films, large, popular and "unconverted" audiences are most readily to be found in the ordinary commercial picture houses. Here at once is a difficulty for a health film—with, for example, an antivenereal disease narrative—as it must often sacrifice scientific and ethical qualities if it is to be a box-office draw.

Then again a propaganda film may often suffer from a wrong type of "supporting" program, as, for instance, at a well known cinema where I saw as a complement to the film "Social Enemy No. 1," another entitled "Ladies Crave Excitement"!!

The production of health films—above all antivenereal disease films—

should preferably be outside the commercial sphere, and the films should be prepared under scientific direction. In addition to the picture houses, there are plenty of useful fields for the showing of such films, as, for example, in the factories. First class films are in fact readily available through the official agencies already mentioned.

SEX INSTRUCTION TO YOUNG PEOPLE

In the campaign against venereal diseases, sex instruction to young people is of basic importance. In my own City of Coventry, much work has recently been done along these lines in the youth centers.

At each center a special meeting is arranged from time to time consisting of three sessions, viz.: (a) a half-hour talk to the girls, (b) a half-hour talk to the boys, and (c) a mixed session on "brains trust" lines. The talks are made by a doctor and the brains trust is composed of a doctor, a youth organizer, and a school teacher.

The talks deal with the nature of the sex organs, and with reproduction. Although the wording of the talks is simple and direct, the scientific basis is preserved. In the girls' group special information is given on menstruation. In each group brief reference is made to the nature and dangers of venereal disease.

At each center, attendance at the sex instruction meetings is of course voluntary and normal club activities are available on the same evenings for any boys and girls who elect not to attend the meetings. The large majority do in fact attend. It is interesting to note that the reaction of the parents of the young people concerned has been universally favorable to this work.

SEX INSTRUCTION IN SCHOOLS

The policy in regard to sex instruction in schools is probably more progressive in America than in Britain

at the present time. In Britain, however, there is a growing advocacy on behalf of this branch of education, and in fact much useful work is already being done on these lines.

There is no doubt that it is easier for the teacher (assuming a proper training for the work) to impart sex knowledge than it is for the parent, for even doctors will say that it is less difficult to tell these things to other people's children than to their own.

It seems clear that no child should leave school without a simple knowledge of the form and functions of the reproductive organs. To achieve this, the teachers should lead up through plant and animal life to the human process. Vocabulary is all important in order that the sordid terms so often picked up by school children may be avoided.

Instruction in simple general hygiene and in the health work of local authorities is also vitally important and this is now pretty general in British schools today. Visits by the older girls to infant welfare centers, etc., and visits by the older boys to waterworks, etc., form an indispensable part of the work.

THE MEDICAL BRAINS TRUST

The "brains trust" idea* has won a wide acceptance and in no quarter is it more popular than among the workers. It represents education in a palatable form. It has the advantage that it deals with points of real popular interest—because the questions dealt with are posed by the listeners themselves. A big attraction is the genuine spontaneity of the answers. The conversational nature of the brains trust session, too, is in happy contrast with the formality of the average lecture or "pep" talk. The brains trust has great possibilities in health education.

* Corresponds with the "Information, Please" pattern.

Recently in the Rootes' Group of large engineering works in England a series of Health Weeks was arranged through the enlightened policy of the managements and in each the program included a Medical Brains Trust. This undoubtedly was the most popular feature.

Before the day of the brains trust session, the workers had been invited to submit their questions, and prizes were offered by the management for the best questions. The entries were judged in secret by a special committee and the best dozen questions were selected to put to the brains trust. Needless to say the members of the trust had no previous knowledge as to the nature of the questions.

The typical scene is a large factory canteen during the lunch hour. There are some 6,000 workers seated at their meal—truly a grand audience. There are four of us on the trust and the question-master. The managing director introduces the question-master, who in turn introduces us. We sit round a table on a platform at one end of the huge canteen with loud-speakers before us.

QUESTIONS AND ANSWERS

At a typical factory brains trust session the following were the questions put and the answers given. The answers will of course be obvious to a medical audience but they are included merely for purposes of completeness.

The first question is a far-reaching one: "Is it not time for a certificate of good general health to be produced as a condition of marriage?" We all agree that a certificate of freedom from transmissible disease—venereal disease, for example—is obviously desirable in respect of persons proposing marriage. It is the majority opinion, however, that medical certificates of fitness at marriage should not be required compulsorily until a strong

antecedent public opinion is more in evidence.

The next question is: "Do you think that work in modern factories is detrimental to the health of middle-aged women who have been drafted to industry?" We note here the reference to modern factories which presupposes good environmental conditions. The view is expressed that the ills of middle age in women tend to be exaggerated. Thus given decent working conditions—and reasonable travelling facilities to and from the factory—war work in the factory is not likely to harm the health of the workers in question.

Now comes the question: "The health of the people in this country has been better in wartime; will the brains trust give the reasons for this?" Rationing and food supplies are obviously a main issue here, and it is generally agreed that present conditions have resulted in a more equitable distribution of essential foodstuffs, and that all get sufficient to maintain health. In regard to child nutrition, the policy of the Ministry of Food in distributing fruit juices is commended. A point that is well brought out is the psychological satisfaction of useful work and the present absence of unemployment.

The inevitable question now follows, viz.: "Can venereal infection occur through any means other than sex relationship with an infected person?" The answer here is—for all intents and purposes, no! The notion that venereal disease can be contracted from infected towels, closet-seats, etc., is largely erroneous. Such an event is in fact extremely rare.

Question number five is: "In con-

nection with the blood donor scheme, what prevents infections like syphilis being transferred from donor to receiver?" The reply is of course that the blood of donors is suitably tested and grouped before possible use.

The next question is of quite a different kind. "Flat feet and malformed feet appear to be very prevalent; what are the causes?" We deal at some length with the factor of incorrect footwear, and indicate the right types of shoes, notably for children. The value of corrective exercises is emphasized.

Time permitted of one more question only at this session, viz.: "School children have regular medical and dental inspections; would it be a good thing if this could be continued after school-leaving age?" Our answer is in the affirmative. It is agreed that regular overhaul by the family doctor and dentist at given intervals would be a good thing for the general population, because by this means departures from the normal would be ascertained at an early stage when treatment would readily be effective. It is mentioned that, in America, life insurance offices commonly offer these facilities free of charge to their policyholders, the idea being to lengthen the lives of persons insured with them.

CONCLUSION

It has been essayed to deal briefly with a few aspects of the theory and practice of popular health education. In spite of all official efforts in this field, there is yet much to be done. The greatest advance of all will come when the family doctor elects to become a missionary of preventive medicine.

THE SECOND WARTIME PUBLIC HEALTH CONFERENCE

THE Annual Meeting held in New York (October 3-5) was again an unqualified success. The attendance (3,984) compared well with the present total membership of 9,163. The program was of high quality. President Felix J. Underwood of Mississippi guided the General Sessions and the Governing Council with the firmness and graciousness and the sure choice of words which make him admired and beloved. As President for 1944-1945, we welcome John J. Sippy of California, the first county health officer to receive this honor; and the choice of Milton J. Rosenau of North Carolina as President-Elect gives delight to all the disciples of the Dean of Public Health in the United States—that is, to all of our public workers, everywhere. The award of the Sedgwick Memorial Medal for 1944 to Ernest W. Goodpasture was a fitting tribute to a scientist whose discoveries underlie much of our practice in the control of virus and rickettsial diseases.

As is natural in a war period, the program this year included fewer new advances in the fields of basic scientific research than has often been the case. In the field of new technics, the extraordinary possibilities offered by the use of DDT were, of course, outstanding; this material gives us methods for the destruction of many insect vectors with an efficiency that is almost unbelievable. The Army Commission on Neurotropic Diseases reported some of its studies on Infectious Hepatitis—the outstanding “new” disease of this war; and demonstrated the production of this infection in human volunteers by feeding virus derived from excretal material. The possible introduction into this country of anthropod-borne encephalitides was discussed. A group from the Michigan School of Public Health presented perhaps the most comprehensive epidemiological study of poliomyelitis ever made, revealing the overwhelming influence of contact infection (stools positive in 75 per cent of familial contacts, in 18 per cent of non-familial contacts, in 2 per cent of non-contacts). In regard to the important question whether the sterilization of air in barracks is justified in routine practice, investigators at Northwestern University (using triethylene glycol) and navy doctors (using ultra-violet radiation) reported in the affirmative; the gain effected in the second of these studies was, however, slight. Investigators from North Carolina

compared the findings from tests of subclinical malnutrition with actual family diets with disturbingly slight concordance of results.

It was the field of administrative practice rather than of epidemiological research which dominated the conference. The Health Officers Section opened its program with a panel discussion on local health administration which was vital and constructive. Discussion was continuously and spontaneously maintained from the floor and every speaker "made sense." To the oldsters in the A.P.H.A., the appearance each year of more and more able and informed and earnest young city and county health officers is a thrilling experience. Methodology in the control of nuisances was helpfully discussed in the Engineering Section.

Outstanding in this field were preliminary reports of Haven Emerson's Committee on Local Health Units, which will give us a framework for a really national health program, with at least minimum basic full-time service (at \$1 per capita) for 1,169 well planned areas covering the entire country—instead of the present mean expenditure of \$.50, with 40 per cent of our population lacking any full-time local health service. The C.A.P. program for a National Reporting Area for health practices¹ will be invaluable in connection with this—or any other—national health program.

It is clearly impossible even to refer to the 36 general and sectional sessions held in New York. The joint session at which a coöperative plan for the health education of industrial workers by the Fort Greene Industrial Health Committee (Brooklyn) aroused particularly wide interest. It is gratifying to note the progress of our two youngest sections, on School Health (organized in 1942) and on Dental Health (organized in 1943).

One of the most striking features of the Conference was its recognition of international health problems. At the first general session Raymond B. Fosdick, President of the Rockefeller Foundation, delivered the Third Annual Delta Omega Lecture on "Public Health as an International Problem," published in this issue of the JOURNAL—a splendidly effective presentation of our common responsibilities as citizens of "One World." The First Special Session, on "Today's Global Frontiers in Public Health" in which representatives from five nations participated, carried our thoughts on this line further, the address of Szeming Sze, of China being particularly impressive. An Association Committee on Pan-American health problems under the chairmanship of Louis I. Dublin is making its contribution; and the fact that our revised report on Communicable Disease Control seems likely to be adopted by at least three other nations is an example of highly practical international service. The Association by official resolution offered its assistance to UNRRA in its difficult tasks; and called for the creation of a new international health organization as a part of the future world order.

The most outstanding problem of the conference was that of medical care. For twenty years or more this topic has come up in our annual sessions; at last, in 1944, it was faced with courage and determination. Mayor Fiorello H. LaGuardia opened the ball at the second general session. With his inimitable vigor he told us "When knowledge is not applied, it's *wicked*" and that "People have a right to medical care"; and he described the program for a voluntary health insurance plan, with complete coverage, for employees of the city and of private industry which will soon go into force in New York City. A discussion before the Maternal and Child Health Section dealt with the problem of medical service for migrant workers and the excellent way in which it has been handled

by the Farm Security and War Food Administrations. A Special Session was devoted to addresses by a group of members of the Subcommittees on Medical Care of the C.A.P. (under the chairmanship of J. W. Mountin), on the content and administration of a Medical Care Program. Excellent programs of this sort have, however, been presented at previous meetings. What is significant about 1944 is that the Association at last took action. On recommendation of the C.A.P., and after full discussion at two meetings, the Governing Council formally adopted the report of Dr. Mountin's Committee on Medical Care in a National Health Program* as the official policy of the Association.

This action puts the A.P.H.A. squarely on record in favor of a national program which shall make available for all the people of the United States complete and adequate medical care of all essential types. It makes it clear that such an end can be attained only by a decentralized but federally aided program; that it must be supported by compulsory insurance plus taxation or by taxation alone; and that it should be administered by a single public health agency at the federal, state, and local levels.

This is a bold pronouncement, which required real courage to adopt. The policy outlined is sound and will, we believe, receive the very serious consideration of legislators concerned with this challenging problem. It is fitting and proper that the first clear and constructive statement of a national program of medical care to be made by any national body of experts should come from the A.P.H.A.—since the health officer represents professional knowledge on the one side and community responsibility on the other. The physician is bound by a Hippocratic oath which calls for the highest standard of service to those individual patients who call upon his skill. The health officer is the one person whose oath of office lays upon him the responsibility of planning for the health of the community as a whole. That responsibility has been assumed—with modesty, but with a compelling sense of public duty—in the adoption of the policy formulated in New York.

* With minor amendments which clarified but in no way modified its objectives.

SHALL WE CONTROL VENEREAL DISEASE?

THE control of syphilis and gonorrhea is a problem which, at this moment, presents a very special challenge to the health administrator. New discoveries open up dazzling prospects of advance; but our hopes are modified by certain serious doubts and qualifications. Statistical results give evidence of tangible achievement; but our experience after the first World War raises the question whether the results of our program—though good—are good enough.

The combined incidence rate of the venereal diseases in the U. S. Army in 1943 (under 30 per 1,000 per year) was less than half the average rate for our army in the first World War. Yet, even with this relatively low rate, gonorrhea was still at the top of the list of infectious diseases in the armed forces and syphilis near the top. Reports on civilian health made to the U. S. Public Health Service, by local health authorities for the seven months of July, 1943, to January, 1944, inclusive, showed 281,537 cases of syphilis and 181,322 cases of gonorrhea, as

compared with 331,421 and 160,000 respectively for the corresponding period of the previous year, with a rate of a trifle over 4.0 per 1,000 for syphilis and about 2.5 for gonorrhea. The lower rate for 1943 as compared with 1942 is, however, obviously influenced by the absence of a large proportion of the young male population; and it is important to remember that it was *after* the first World War that a true epidemic of syphilis and gonorrhea swept over the world, affecting neutral as well as belligerent countries.

The development of new and more effective methods of treatment is a major factor on the favorable side of the ledger. Dr. George Baehr, in an address before the Committee on Tuberculosis of the State Charities Aid Association of New York, last spring, said: "The recent introduction of rapid treatment methods for early syphilis has made it possible for the first time to eliminate the disease. The five day trip technic for massive arsenotherapy, and subsequent modifications, with and without the artificial induction of fever, can cure 80 to 90 per cent of patients with early syphilis, and render them non-infectious within a week." It is true that with the use of powerful arsenicals severe toxic reactions will sometimes appear and occasionally death will result. But the 18 month procedure, in use for over thirty years, also had some untoward results; and, since less than a quarter of the patients treated by this old method completed their course, it is clear that the new modes of using arsenicals represent a very real advance. Furthermore, as the sulfa drugs followed serum in the treatment of pneumonia—so penicillin has followed rapid application of arsenicals in the treatment of syphilis. "The results of penicillin treatment are at least as good as massive arsenotherapy, and there are no toxic effects whatever. Eighty to 90 per cent of all patients with early syphilis can be rendered non-infectious and perhaps cured within a week. Sufficient time has not yet elapsed to speak positively of a cure, but the results are most encouraging." Even more dramatic in a way than these striking improvements in the treatment of syphilis is the fact that heat treatment and the use of sulfa drugs and penicillin have now made possible the prompt and effective treatment of gonorrhea; for the attitude of health officers toward this disease was—until five years ago—almost completely pessimistic.

On the other hand, the advances in the therapy of syphilis and gonorrhea create new problems for the health administrator. A certain proportion of cases of early syphilis which receive rapid arsphenamine treatment or penicillin treatment will be apparently cured without the elimination of the spirochetes and will relapse; and Koch, Mathis, and Geiger¹ found positive cultures in 32 per cent of asymptomatic cases of treated gonorrhea. Many more cases of syphilis successfully treated by modern methods will become susceptible to reinfection than was the case with older and slower procedures; therefore, it is vitally important to seek out the primary source of infection (to which such cases may be again exposed) and to discover the contacts whom they may have infected before coming for treatment.

Clearly, the use of improved treatment methods intensifies the need for that rigorous epidemiological control which will remain the basis of our public health program in this field. Syphilis and gonorrhea are not vague and intangible social plagues; they are communicable diseases, proceeding—in a given community, at a given time—from a relatively small number of foci. They can be controlled by what Dr. W. L. Munson of the New York State Department of Health once described as "sole-leather epidemiology," followed by persuaded or enforced treatment. What can be accomplished is well illustrated by the work of the Institute

for Control of Syphilis of the University of Pennsylvania Hospital. Kresge² reports that, of 4,861 syphilitic draft rejects followed up, 72 per cent were under treatment or were brought under treatment, at a cost of \$2.13 per case.

In most communities it is the health department which must take the lead. It is the health officer who must decide whether we shall control syphilis and gonorrhea, whether the new technics at our disposal shall be used to good effect, whether we shall conquer these diseases as we have conquered diphtheria.

Dr. Baehr tells us that: "The time has come when the public health services, state and local, as well as federal, must step in and take over the problem of therapy as a routine public health measure. The establishment of Rapid Treatment Centers in many parts of the country, with the assistance of the U. S. Public Health Service and with funds made available by the Congress, is an example of what should now be done on a broader scale. Rapid treatment should be made freely available without charge to every person with early syphilis, on the one condition that he or she provide the health department with information which will enable them to bring the contacts under treatment. Rapid treatment with penicillin requires hospitalization for a week. Beds must be made available temporarily until the disease has been wiped out.

"Now, let a new broad gauge viewpoint animate the public health services and the medical profession! We must deal with syphilis as we would with plague, cholera, or any other highly communicable disease, and wipe it out by providing adequate funds and facilities for free diagnosis and treatment for all infected persons and their contacts. The control of this widespread disease which infects hundreds of thousands each year is now in our hands if we will place the responsibility for treatment wholly in the public health services and, as with other highly communicable diseases, cease worrying about infringing upon the vested interests of the private practitioner. As a practitioner of more than 35 years, I call upon the public health services to seize this new opportunity and do a complete job!"

MORE POWER TO THE PUBLIC HEALTH SERVICE

WE have referred in an earlier issue¹ to the legislation of last spring in regard to the U. S. Public Health Service. A second and even more important law was enacted during the summer, sponsored by Representative Bulwinkle.²

This Act for the first time brings together in compact and orderly fashion various laws applicable to the Public Health Service which have been accumulating for more than a century and a half. Numerous statutory amendments imposing new duties and authorities, couched in different terms, and often providing new procedures without expressly repealing previous conflicting requirements have not only left gaps in the operating framework of legislation but have created serious ambiguities and inconsistencies. The new law brings together all these various provisions, reenacts those which are active and permanent, repeals those which are obsolete, eliminates inconsistencies in language and broadens powers that have been found to be too restricted.

Among the new substantive provisions, it is gratifying—in view of the great

importance of public health nursing in our present program—to note that nurses, as well as scientists in such fields as biology and zoölogy, are now made eligible for appointment to the regular commissioned corps of the Service; and that provision is made for allowances for female commissioned officers on account of actual dependents.

The authority to formulate regulations, which under previous laws was confused and illogical, is now clearly allocated to the President, the Administrator, and the Surgeon General, in accordance with the nature and importance of these regulations. Quarantine laws and regulations may now be applied specifically to civil air navigation.

The limits of appropriations for grants to the states for public health work are increased to \$20,000,000 annually, of which \$2,000,000 is available for direct federal expenditure in relation to such grants. A new authority is added for grants for the control of tuberculosis in the sum of \$10,000,000—with a very broad definition of what such control may include.

Particularly valuable are many provisions in this bill which give the Service increased freedom of action in regard to administrative detail. Special emergency positions can be authorized by the President in time of war or other emergency; restrictions to annual allotment and quarterly payment of grants to states are replaced by a provision for allotments and payments to be made “from time to time”; there is to be freedom for emergency treatment at Service Hospitals for those not ordinarily eligible; and considerably greater flexibility in procedures for isolation and quarantine. The scope of the research program of the Service will be materially broadened.

The 78th Congress has taken time off from “politics” to produce at least one highly constructive piece of legislation.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted.

Clinical Evaluation of the Rehabilitation of the Tuberculous—
By Louis E. Siltzbach, M.D. New York: National Tuberculosis Association, 1944. 70 pp. Illus. Price, \$.50, paper; \$1.50, cloth.

To be foremost in anything on this busy planet is proud achievement. That distinction must be awarded the Committee for the Care of the Jewish Tuberculous of New York City, in devising and perfecting a scheme for the discovery of tuberculosis cases, their adequate care and treatment, and restoration to social and economic usefulness. The crowning achievement has been the successful operation of a garment manufacturing plant, planned and built for the part-time and full-time employment of tuberculous men and women. There are 170 employees, accepted without regard to race, color, or creed. None but those who have attempted a rehabilitation program can fully appreciate what a difficult road has been traversed by the promoters.

Though it is said that every institution is the lengthened shadow of a man, I see here two shadows, cast by Fred M. Stein and Edward Hochhauser, respectively President and Executive Secretary of the committee.

This clinical evaluation gives the historical background, states the philosophy upon which the service is built, describes the shop and the methods employed. The statistics have been meticulously tabulated and interpreted.

The late Dr. Lawrason Brown once remarked that no physician should attempt the rôle of statistician. Dr. Siltzbach has not committed this error

but has sought the aid of well known statisticians. That makes the booklet of enormous value to students of rehabilitation. It constitutes a model for those who wish to make similar surveys. Dr. Siltzbach's long connection with the program covering many years insures clinical accuracy.

The results of a quarter century should stimulate others to emulate the example of the Committee for the Care of the Jewish Tuberculous, Inc.

H. A. PATTISON

Guiding the Normal Child—
By Agatha H. Bowley, Ph.D. New York: Philosophical Society, 1943. 174 pp. Price, \$3.00.

The purpose of this book is to present a brief review of the developmental patterns from birth to adolescence. The book has been written for young teachers in training, but should be useful not only to parents but to students working in the fields of pediatrics, public health, and to others who may have responsibility for the care of children. The growth and development of the child is discussed primarily from the emotional point of view, although the relationship between physical, mental, and emotional well-being is emphasized frequently in the text. In a book of this kind, each chapter is of necessity brief and pointed, but should serve to open the way to further study which will be aided by the authoritative bibliography following each chapter.

The best chapters are those dealing with young children from infancy up to the middle years. The chapter on adolescence is all too brief, but this

only serves to emphasize the inadequacy of our knowledge of this age group. Many of the suggestions on ways of helping children to develop good behavior patterns are of real practical value. The case histories, while they do lend color to the chapters, and are undoubtedly instructive, because of their brevity may give the student the impression that solution of obviously difficult problems of behavior are simple and come about quite easily when an adjustment is made. The English approach is slightly different from that used by many of our American authorities in this field, in that there appears to be less emphasis on scientific developmental data, and more on the interpretation of behavior. This book can be recommended for those who wish orientation in the field of emotional growth and development of children. It should be of special benefit to teachers and school nurses.

GEORGE M. WHEATLEY

Textbook of Physiology—By W. D. Zoethout, Ph.D., and W. W. Tuttle, Ph.D. (8th ed.) St. Louis: Mosby, 1943. 728 pp. Illus. Price, \$4.75.

The new edition of the *Textbook of Physiology* brings this valuable book up to date and thus continues its usefulness to students and teachers of physiology. Like the earlier editions, it is written in a style suitable for students in colleges and normal schools who have had basic science courses but who for the first time are being introduced to an advanced scientific discipline.

The authors have deliberately avoided the production of the exhaustive type of book which most medical students demand, and have even further condensed the purely physiological content to make room for necessary background material from chemical, anatomical, and general biological fields. The first four chapters are, in

fact, devoted almost exclusively to such fundamental topics. Throughout the book there is ample exposition of animal and human anatomy so that the discussions of functions are in correctly concrete terms.

The volume is noteworthy in a number of details, especially the figures in the text which number more than 300. They are almost invariably clear and to the point and many will be recognized by the more mature reader as classical illustrations from the literature of physiology. The index is excellent, and a large glossary of terms will be found useful by students. References to original papers are lacking, but a brief list of monographs and reviews is given.

ROBERT W. CLARKE

A National Health Service—Presented by the Minister of Health, Department of Health for Scotland to Parliament by Command of His Majesty. New York: Macmillan, 1944. 85 pp. Price, \$.75.

Everybody should read *A National Health Service*, known as "A White Paper." It is an official document from the British Ministry of Health outlining the proposals of the Government in regard to medical and health services. The opening sentence of the introduction tells the story:

The Government have announced that they intend to establish a comprehensive health service for everybody in the country. They want to ensure that in the future every man and woman and child can rely on getting all the advice and treatment and care which they may need in matters of personal health; that what they get shall be the best medical and other facilities available; that their getting these shall not depend on whether they can pay for them, or on any other factor irrelevant to the real need—the real need being to bring the country's full resources to bear upon reducing ill-health and promoting good health in all its citizens.

This is a breath-taking proposal. It is startling in its simplicity, in its com-

prehensiveness and in the confidence with which it is entered upon.

The White Paper contains 85 pages of rather small type, closely printed material. It goes into all pertinent phases of the subject, but, of course, not into much detail on any one of them. It outlines the present situation. It explains how it came to be that way. It describes, in somewhat general terms, the general administrative structure of the proposed national medical service with its important centralized responsibilities and its highly important local organization and services. It explains how hospitals fit into the picture; also general medical practitioners, and health services.

It gives some idea as to how it all is to be financed. There is to be no payment for services rendered. Everybody is to have an equal claim for a high grade of medical care. There is to be no compulsion about it, except in the matter of paying one's taxes. In a sense it proposes to substitute a national operating health service for a national health insurance plan for employed persons and in place of chaotic arrangements in regard to all not employed. Broadly speaking, the new plan is to be financed somewhat more than one-third from the national treasury, an equal amount from the local treasury, and the remainder, slightly more than one-quarter, from the social insurance funds. Much remains to be worked out, of course, as to the details of organization and of finance, but the British people, through their government, have put their hand to the plow and it is safe to say that the furrow will be turned.

It is really delightful to read this White Paper because of its simplicity, comprehensiveness, and straightforwardness. After being obliged to read or to hear all the yelling and yapping, squalling and squawking that we have been putting up with in talk about the

Wagner-Murray-Dingle Bill (most of which talk shows no sign whatever of any knowledge of the Bill, still less of any serious estimate of its merits and demerits, and it has both), to turn to this British White Paper is like stepping out of an overcrowded, overheated, overnoisy room into the clear, cool atmosphere of out-of-doors.

HOMER FOLKS

Laboratory Methods of the United States Army—By James Stevens Simmons, and Cleon J. Gentzkow. (5th ed.) Philadelphia: Lea & Febiger, 1944. 823 pp. Price, \$7.50.

In this fifth edition of the manual, the same sections of subject matter are included as were included in the previous edition. These sections are headed Clinical Pathology, Chemistry, Mycology, Bacteriology, Rickettsiae and Filterable Viruses, Protozoölogy, Helminthology, Entomology, Pathology, Special Veterinary Laboratory Methods, and Statistical Methods. In general an attempt has been made to include laboratory methods required by recent advances in medical practice and control of communicable diseases. Thus, for example, laboratory procedures incident to the control of sulfonamide and penicillin therapy are included.

If this volume had been intended to serve as a highly condensed outline of general methods used in the United States Army, these methods to be supplemented by more detailed textbooks and manuals, its purpose would have been achieved adequately. However, it is stated in the preface that the book is intended as "a manual describing practical methods for use in the medical and sanitary laboratories of the Army." It is the opinion of the reviewer that this book has not accomplished its stated objective and that this is due primarily to the fact that an attempt has been made to include far too much material in the space utilized. As a

result, most procedures are so limited in detail and explanation that only an expert on the particular subject could intelligently conduct the laboratory procedures without access to additional library facilities. As examples, the serological grouping of streptococci and the identification of members of the genus *Shigella* are dealt with too briefly to permit identification by the methods presented; the rapid identification of *Hemophilus influenza* in spinal fluids by direct typing and its satellite growth with staphylococci are not mentioned; the sections on entomology and mycology are too sketchy to be of any real value in practical laboratory investigation.

As a whole the text is relatively free from inaccuracies. However, a few definitions are presented which are not generally accepted; for example, the definition of *thallus*, page 365. The index is quite complete.

No doubt this manual should be included in the library of each large general diagnostic laboratory, but, in the opinion of the reviewer, it is not as valuable as a sole source of laboratory procedures as are other existing manuals. HERBERT C. BATSON

Education and Health of the Partially Seeing Child—By *Winifred Hathaway*, Associate Director of the National Society for the Prevention of Blindness—Published for the National Society for the Prevention of Blindness, by Columbia University Press, New York, 1943. 216 pp. Price, \$2.50.

It is estimated that between 22,000 and 42,000 elementary grade children have visual deficiencies severe enough to classify them as partially seeing. The failure of school and health personnel to locate these children denies them their rightful share in the education they are entitled to under our democracy.

Three major problems associated with

developing a plan for the education of the partially seeing child are: determining the children that should be selected, finding these children, and devising the means by which educational opportunities suited to the needs of these children can be made available. There is a mistaken notion that only children with refractive errors like myopia, hyperopia, and astigmatism need special educational facilities. The recommendation of this book is to consider: (1) children with visual acuity between 20/70 and 20/200 in the better eye after all medical and optical help has been provided; (2) children with serious, progressive eye difficulties; (3) children suffering from diseases of the eye or diseases of the body which seriously affect vision, e.g., measles; (4) children with eye operations that result in the need for readaptation of the eye or psychological readjustment; and (5) children with crossed eyes or other muscle anomalies.

These children may be located through periodic medical and psychological examinations if properly given. A recommended procedure for visual acuity as a screening process is included in the appendix of this book. Final diagnosis of visual deficiency is dependent upon the examination of an ophthalmologist.

Once these children are selected, it is important that they have careful educational and ophthalmological supervision. This calls for the development of special facilities, well prepared teachers, and access to medical health service.

It has been demonstrated that children handicapped by visual deficiencies are capable of achievement comparable to that of children with normal vision, *provided* educational facilities and procedures are adapted to meet their needs.

Public health workers—nurses, health officers, health educators—in their contacts with schools should find this book

helpful. Chapters on program planning, school health services, teacher selection and preparation, conducting and financing classes, preparing the classroom for the partially seeing child; teaching procedures, curriculum content, guidance, and community responsibility present basic information.

This book may be thought of as an authoritative and essential handbook and guide to all those with professional responsibility for the education, health and general welfare of children.

MABEL E. RUGEN

Statistical Reporting in Public Health Nursing—By Margaret L. Shetland, R.N. New York: Guidance of Records Committee and Cost Analyses Committee of N.O.P.H.N., 1944. 56 pp. Price, \$.50.

This handbook is a revision of the smaller handbook entitled "Suggestions for Statistical Reporting and Cost Computation in Public Health Nursing," which was compiled in 1937 by a subcommittee representing the Records Committee and Service Evaluation Committee of the National Organization for Public Health Nursing. This last revision was made with assistance from the Records Committee and the Cost Analyses Committee of the N.O.P.H.N.

The 1944 edition, like the earlier editions, deals with statistical reporting, not with case recording. In clear, concise terms the writer indicates the essential principles underlying an effective reporting system. A distinction is made between statistics that are generally considered to be essential for all agencies to collect regularly, and data that are more significant when tabulated for special studies.

Methods of collecting and using both types of data are suggested. Cases, visits, and other units of enumeration are defined in simple terms which should aid in eliminating much of the

confusion that now exists in reporting public health nursing activities due to variations in interpreting terminology.

In describing the revised method of computing the average cost of the visit as recommended by the N.O.P.H.N., the writer points out that the Cost Analyses Committee is fully aware of the limitations which the present method presents in calculating the cost of public health nursing services because of the ever increasing number of activities other than visiting which the nurses are called upon to do. Various methods of cost computation based on other units of service are being devised, but they are not discussed in the handbook because they are as yet experimental.

The careful arrangement of the contents, with the inclusion of a selected list of references and a good index, make this handbook a useful reference book for individual public health nurses as well as a splendid guide for the use of official and nonofficial agencies in collecting and reporting essential data relating to all phases of public health nursing with increasing comparability.

The writer points out that, due to the many changes in programs necessary to meet wartime needs, some of the material in the handbook is tentative, and conclusive instructions on some phases of the work would be considered premature at this time. Encouragement is given to agencies for continuing work on problems relating to conformity in statistical reporting and more satisfactory computation of cost of services.

MARY D. FORBES

Plenty of People—By Warren S. Thompson. Lancaster, Pa.: Jacques Cattell Press, 1944. 246 pp. Price, \$2.50.

This is a valuable discussion of the population problem by a leader in the field. It is neither an exhaustive nor a technical treatise. That the author

produced in 1942 in his volume entitled "Population Problems." The fifteen chapters cover such subjects as the growth of population since 1800, the birth rate, the factors in the decline of the birth rate, the death rate, war and population growth, the future population of nations, political and economic implications of differential national growth, the distribution of population, migration, effects of age changes, social and economic effects of the slower growth of populations, the biological fitness of the people, minorities and population policies, with especial reference to a population policy for the United States. Together, they provide a readable summary to orient the lay reader in the essentials of the population problem.

It is an attractive feature of this volume that it highlights the significance of population changes for human welfare. Until recently, this field had little or no interest for the American public. There seemed to be no particular need for an American population policy. Our population increased rapidly; our resources were ample and we had no quarrels with other nations. The scene has shifted, however, and population questions have become a pressing concern for intelligent people in our country. This book should help those who want to know what is happening, not only here but throughout the world, in terms of numbers of people, their relation to natural resources, changes that are going on, and how all of this affects national welfare and future relations between nations.

Professor Thompson is well qualified to discuss these problems. He has approached his task not only with the expert knowledge of the demographer but also with the matured judgment and the wise social philosophy of the trained economist and sociologist. Workers in the field of public health will find much of value in this little book and will be

grateful to the author for pointing out the significance of their work in the larger field of international relations.

THOMAS D. DUBLIN

The Road to Safety Series—By Buckley, White, Adams, Silvernale (rev. ed.). New York: American Book Company, 1943.

A. Away We Go,	\$.28
B. Happy Times,	.80
C. In Storm and Sunshine,	.84
D. In Town and Country,	.88
E. Here and There,	.92
F. Around the Year,	.96
G. On Land and Water,	1.00
H. Who Travels There?	1.04

The Road to Safety is a revised series of eight books intended to combine good reading practices with effective safety instruction. The stories have been adapted from well known books and magazines. The material is based on safety and graded from the standpoint of reading ability from pre-primer to the 6th grade.

The following safety subjects are covered in each book and presented in a different form to fit the needs of each specific age group:

School Safety
Fire Prevention
Street Safety and Travel
Home Safety
Winter Safety
First Aid
Safety Out of Doors
Vacation Safety

Numerous illustrations accompany the text.

Each book is meant to be used with a corresponding Workbook: questions and answers, sentence completion, coloring pictures, matching exercises, etc., are designed to provide a more thorough understanding of the stories read and the conceptions gained.

The series also includes three Teacher's Manuals which contain bibliographies of material for story telling

and additional reading matter, dramatizations, library activities, aids in teaching phonetics and in planning safety activities, etc.

The approach to the teaching of safety throughout the series is a positive one and mostly indirect. True courage and the desire for good adventures are fostered, while fear and gruesomeness are left out. The authors have prepared the material to meet the needs of children for safety education throughout the entire nation, whether living in large cities, small towns, or rural communities. While the material is used during the reading periods, the subject matter at the same time introduces the children to safe habits and attitudes, knowledge and skills, thus combining reading practice and safety education without adding another subject to the curriculum.

In selecting the presented reading material the authors utilized their experiences gathered over a period of years in Cleveland Schools (Ohio). These were the results of studies which not only dealt with the reading needs of pupils, but also included analyses of thousands of child accident reports.

The books are not numbered according to grade, but lettered from A to H, which suggests a certain amount of flexibility as to their use for certain age groups.

HERBERT J. STACK

Contagious Diseases—By W. W. Bauer. (2nd rev. ed.) New York: Knopf, 1944. 188 pp. Price, \$2.50.

"Modern methods for the control of communicable disease and the prevention of epidemics are available and should be used to the greatest possible extent. It is only when parents understand what these measures are and how to use them that their effectiveness can be fully realized."

This statement appears as the theme which runs through Dr. Bauer's excellent little book. It is a book for

intelligent parents. There is discussion of the bacteriology and immunology of the common communicable diseases in terms that the layman can understand, and there is explanation of the household and community procedures used to break the chain of transmission of disease.

Bacteriology, control procedures, home nursing, and then specific illnesses are covered in individual chapters. Much excellent information is presented; much common misinformation is corrected. Health workers can learn something about presentation of information to lay groups by reading this book. Some health departments will wish that their regulations were more in line with existing knowledge after parents in their jurisdictions have digested the book's contents.

This guide for parents is carefully written, is scientifically accurate, and is in understandable language. It will soon find a useful place for itself.

WENDELL R. AMES

Osler's Principles and Practice of Medicine—By Henry A. Christian. (15th ed.) New York: Appleton-Century, 1944. 1498 pp. Price, \$9.50.

The tradition of this recognized textbook of medicine has been maintained in this 15th edition. This new revision, appearing within 18 months of the previous one, brings the information in the textbook up to date and includes many recent developments, particularly from the point of view of the requirements of the medical personnel of the Armed Forces. In this connection the inclusion of recommendations from the Office of the Surgeon General of the United States Army concerning diseases of military importance is extremely valuable. Particular attention has been given to the present status of tropical diseases and other diseases of importance in the military effort.

It is too easy in evaluating a work as

extensive as this to find omissions and defects, but certain of these are worth comment. Since this edition is particularly directed toward use by medical personnel of the Armed Forces, the lack of reference to homologous serum jaundice is a striking omission, and the section on war gases contains little specific information. The recommendations for immunization against diphtheria and pertussis are not in accord with modern public health practice. The indication that sulfapyridine is the

drug of choice for the treatment of Friedlaender's bacillus infections should be corrected. The references to source material are more numerous in this edition than in previous ones, but still are not adequate for the needs of the practising physician.

The textbook presents the current basic facts of internal medicine in simple, readable style and in excellent format. It will provide orientation to physicians desiring to keep up to date in medicine. DAVID D. RUTSTEIN

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

When the Lines Cross—In 1909 tuberculosis stood first and diabetes sixteenth in rank among the causes of death. Today the relative standing is seventh and ninth. In some states the curves have crossed. Herein lies the text for a dozen sermons on public or private health.

ANON. Diabetes and Tuberculosis—A Comparison. Stat. Bull., Met. Life Ins. Co. 25, 6:3 (June), 1944.

Potpourri—This fast running blow-by-blow account of many comments on recent changes in the school health program, in which almost every variety of specialist and Dorothy Nyswander take part, is worth your while. Nothing significant could be said about it in this brief note.

ANON. The Changing School Health Program. Pub. Health Nurs. 36, 9:478 (Sept.), 1944.

Once It Was Constipation or Sluggish Liver—Though this is a medical paper there are two signs-of-the-times sentences in it which deserve to be preserved in the annals of public hygiene. "In the minds of the public, lack of energy tends today to mean lack of vitamins. Our experience lends no support to the theory that vitamin deficiency seriously affects the health of a large percentage of the population."

ALLAN, F. N. The Differential Diagnosis of Weakness and Fatigue. New England J. Med. 231, 12:414 (Sept. 21), 1944.

About Detergents, Bactericides and Washers—Recommended methods for restaurant dish washing are described in detail. Experience shows, says the writer, that health officials will achieve better results by persuasion

than policing. Dish washers will wash with a better will if they know the reasons than if they hear threats only. Training courses are recommended.

ANDREWS, J. Methods of Sanitizing Eating and Drinking Utensils. Pub. Health Rep. 59, 34:1103 (Aug. 25), 1944.

There's Nothing Like a Snappy Title—You will discover here a lot of information about the eyes of the Okies (and others). There is one item which should be paraded before deluded believers in racial superiorities: in all ages, Negroes were found to have less defective vision than whites.

GOVER, M., and YAUKEY, J. B. Physical Impairments of Members of Low-Income Farm Families—11,490 Persons in 2,477 Farm Security Administration Borrower Families, 1940. I. Characteristics of the Examined Population. II. Defective Vision as Determined by the Snellen Test and Other Chronic Eye Conditions. Pub. Health Rep. 59, 36:1163 (Sept. 8), 1944.

Human Reclamation—To the British Isles has fallen the honor of most of the pioneer work in rehabilitation says this writer. Among the many pre-war establishments for the rehabilitation of the disabled, was Letherhead Cripple's Training College (a dreadful name if ever I saw one), but it was the war that put this human reclamation project on the map. There are three schools of thought about the subject which will interest American rehabilitators: to them I commend the paper.

GRIFFITHS, H. E. Rehabilitation. J. Roy. Inst. Pub. Health & Hyg. 7, 9:225 (Sept.), 1944.

Prophylactic Values in Sulfa Drugs—Among young men in military training camps it was found that daily

doses of 1 gram of sulfadiazine resulted in a 50-75 per cent reduction in incidence of respiratory and streptococcic infection. It appears that the reduction in rheumatic fever parallels the respiratory diseases.

HOLBROOK, W. P. The Army Air Forces Rheumatic Fever Control Program, (and) COBURN, A. F. The Prevention of Respiratory Tract Bacterial Infections. *J. A. M. A.* 126, 2:84 (Sept. 9), 1944.

Last Look at the Late Flu Epidemic—After reviewing the statistics, the writers conclude that the 1943-1944 winter outbreak of influenza was larger than any epidemic since 1928-1929, but caused only 8 per cent as many excess deaths as did the 1918 pandemic.

HOLLAND, D. F., and COLLINS, S. D. The Influenza Epidemic of the Winter of 1943-44. In the United States: A Preliminary Summary. *Pub. Health Rep.* 59, 35:1131 (Sept. 1), 1944.

A Plan That Has Started to Roll—Here's a new story of an Ohio county school health committee which approved and put into use an individual student cumulative health record and a lot of other measures to improve the school health program. Then local committees were found necessary. What the first of these did in its initial meetings is recounted. This seems to be an important paper.

KERR, L. E. Coördinating Health Education. *Pub. Health Nurs.* 36, 9:463 (Sept.), 1944.

And the Sanitary Facilities Were Poor, Too—In a survey of small industries in the lower East Side of New York these arresting statistics were unearthed: none of the plants with less than 250 employees had nursing services while 64 per cent of those employing more than 250 had full-time nursing care. Only 88 per cent of all plants had medical services of any kind.

KRESKY, B., and ROSENTHAL, T. A Survey

of Medical and Sanitary Facilities in Small Industrial Establishments. *J. Indust. Hyg. & Toxicol.* 26, 6:201 (June), 1944.

Your Beetle-Browed Attention, Please!—Syphilis being the treacherous kind of disease it is, we must wait for the final answer, but penicillin now seems to be it. Penicillin has a profound effect in early syphilis on disappearance of organisms, healing of lesions, and serological reversal. In late syphilis, also, the apparent results are much too good to be entirely true.

As you must be aware by now, the object of this bibliography is to cajole, inveigle, or otherwise to seduce you to hunt out and ponder over the papers here annotated. Well, if the poor, inadequate paragraph above, sends you to these undoubted papers-of-the-month, then all the reams of good white pulp used upon this section during the past two decades may not have been totally wasted.

MAHONEY, J. F., *et al.* Penicillin Treatment of Early Syphilis, MOORE, J. E., *et al.* The Treatment of Early Syphilis With Penicillin, (and) STOKES, J. H., *et al.* The Action of Penicillin in Late Syphilis. *J. A. M. A.* 126, 2:63 (Sept. 9), 1944.

Heresy—Concludes the writer in these words: it probably accounts for the ability of you and me to eschew with impunity such protective foods as milk and spinach, if we don't like them. It is an important phase of man's capacity to survive and thrive in all regions of the earth. The definition of "it" you will find in the title below.

MITCHELL, H. H. Adaptation to Under-Nutrition. *J. Am. Dietet. A.* 20, 8:511 (Sept.), 1944.

Contemporaries of "Dem Bums"—You really should read this account of the program of wide-awake industrial health committees, so I shall say nothing here that might sate your appetite for the news.

SHOSTAC, P. An Industrial Health Com-

mittee Grows in Brooklyn. Channels. 22, 1:1 (Sept.), 1944.

What about Your Department?—Arguments are marshalled here to support the thesis that a campaign to prevent malnutrition is a legitimate function of a local health department, and that the division of nutrition should act as the centralizing agency for the better nourishment of the people.

SMITH, H. H. Nutrition and Public Health. Nutrition Abstr. & Rev. 2, 9:257 (Sept.), 1944.

Bearing the Stigma of "Crack Pot"—Psychiatric examinations of selectees demonstrate an alarming amount of ill health in our communities, and makes obvious the need for comprehensive mental hygiene programs: say these competent commentators.

WAGGONER, R. W., *et al.* Psychiatric Selection of Men for the Armed Forces. J. A. M. A. 126, 4:221 (Sept. 23), 1944.

You Take Your Choice—Non-tuberculous inmates of a mental hospital were vaccinated against tuberculosis and compared with a control group. The findings support the thesis that a heat-killed, tubercle bacillus vaccine has some protective value and might be used by those who are subjected to unusual risks of tuberculosis infection. To confuse the innocent bystander a companion paper reports that the vaccine used in a free population was not attended by significant results.

WELLS, C. W., *et al.* Results Obtained in Man with the Use of a Vaccine of Heat-Killed Tubercle Bacilli. Am. J. Hyg. 40, 2:116 (Sept.), 1944.

ASSOCIATION NEWS

OFFICERS, 1944-1945

President, John J. Sippy, M.D., Stockton, Calif.

President-Elect, Milton J. Rosenau, M.D., Chapel Hill, N. C.

Vice-Presidents, Malcolm R. Bow, M.D., Edmonton, Alta., Canada

Carlos E. Paz-Soldan, M.D., Lima, Peru

Treasurer, Louis I. Dublin, Ph.D., New York, N. Y.

Executive Secretary, Reginald M. Atwater, M.D., Dr.P.H., New York, N. Y.

Chairman of Executive Board, Abel Wolman, Dr.Eng., Baltimore, Md.

New Members of Executive Board:

Pearl L. Kendrick, Sc.D., Grand Rapids, Mich.

Charles F. Wilinsky, M.D., Boston, Mass.

Sedgwick Memorial Medal for 1944 Awarded to Dr. E. W. Goodpasture

THE award was made on October 3, 1944, during the Seventy-third Annual Meeting of the American Public Health Association in New York, N. Y.,

by Dr. C.-E. A. Winslow, Chairman of the Sedgwick Memorial Medal Committee. In presenting the medal, Dr. Winslow said:

"One of the peculiar charms of public health lies in the breadth of its scope and the diversity of the brotherhood enlisted in its service. The Sedgwick Medal has been awarded in recent years to administrators, teachers, bacteriologists, epidemiologists. Leaders in engineering, in vital statistics, and other areas of public health will no doubt be recognized in the future.

"Tonight, as when we honored Smith and Park, Jordan and Zinsser, we crown achievements in the basic fields of laboratory research which underlie as a sure foundation all our machinery of health administration.

"Ernest William Goodpasture is a pathologist—the first representative of that field except Theobald Smith to receive the Sedgwick Medal. He was born at Clarksville, Tenn., in 1886; received his B.A. degree at Vanderbilt in 1907, and his M.D. at Johns Hopkins in 1912. He is an honorary Master

ERNEST W. GOODPASTURE, M.D.

SEDGWICK MEMORIAL MEDAL

of Science (Yale) and Doctor of Science (Chicago). Dr. Goodpasture began his career in pathology at the Hopkins (1912-1915) and at the Peter Bent Brigham and Harvard (1915-1921). He obtained valuable experience as Chief of the Department of Pathology and Bacteriology at the University of the Philippines (1922) and at the Singer Memorial Research Laboratory of Pittsburgh (1922-1924). He studied as a Rockefeller fellow in Vienna in 1924-1925; and since 1925 has been Professor of Pathology at Vanderbilt.

"Dr. Goodpasture is a member of the National Academy of Sciences; and has been Research Medallist of the Southern Medical Association (1937); President of the American Society of Experimental Pathologists (1939); Vice-President of the A.A.A.S. (1940); and he received the Kober Medal of the Association of American Physicians in May of the present year.

"Dr. Goodpasture is an outstanding teacher of pathology and, through his pupils as well as through his own direct contacts, has exerted a notable influence on the teaching of this fundamental branch of medical science. He developed new methods of staining the inclusion bodies apparent in many virus

diseases; and, in general, the results of his investigations on vaccinia, on poliomyelitis, on fowlpox, on molluscum contagiosum, on rabies, on herpes, on influenza, have been of primary significance in revealing the secrets of our virus enemies and in making possible our defenses against their ravages.

"As one example of the influence of Goodpasture's researches we may cite his studies on mumps which (as carried forward by Enders and Cohen) make it possible to separate those who are immune to this disease from those who are susceptible in any human population and to recognize hitherto inapparent infections—points of very great practical importance in administrative control.

"Even more far-reaching in its effects has been Goodpasture's work on vaccinia in the developing chick and on the cultivation of viruses and rickettsiae in the hen's egg, which laid a cornerstone of our knowledge in regard to the cultivation of viruses. It has proved of primary importance in the preparation of vaccines against the various forms of typhus fevers and yellow fever. The Army has recently ordered 50 million eggs for the manufacture of influenza vaccine, an experiment in

global epidemiology of major significance for which Goodpasture paved the way in his laboratories at Vanderbilt.

"There could be no better example of the farflung influence of laboratory research in the field of public health. It is an episode which would have stirred the imagination of William Thompson Sedgwick, whose work on the microbiology of water and milk and ice and air laid similar laboratory foundations for administrative procedures half a century ago.

"It is a privilege for the American Public Health Association to confer its highest honor on Ernest William Goodpasture."

In accepting the award Dr. Goodpasture made the following reply:

"It is a blessing when on rare occasions personalities arise in our midst who, because of their peculiar gifts of character and accomplishment, are representative and symbolic to us of our ideals. For students and devotees of the principles and practice of public health in America, William Thompson Sedgwick was such a man. That I am permitted on this occasion to acknowledge with you his spiritual leadership is a privilege and an honor I treasure most highly.

"Although I was working in Boston at the height of his career at the Massachusetts Institute of Technology, I missed the privilege of contact with him. Nevertheless I was aware of the impact of his influence and his preëminence.

"One of the qualities such men have in high degree I believe, is the quality of vision, inspiring faith. Dr. Sedgwick was a pioneer and as a pioneer his work was not supported by a full realization of its potentialities, but by a knowledge of the needs of his time and a faith in himself, in his students, and in his methods to accomplish a revolutionary epoch in the preservation of health.

"Today we can appreciate fully the

wisdom of his foresight and be witnesses ourselves to the genuineness of his prescience and the effectiveness of his labors as teacher and as investigator."

"Indeed, in a brief span of years we have built a civilization for the integrity and survival of whose structure the application of the principles and technics advocated, devised, and practised by him and by the membership of this Association are no longer merely desirable, but essential.

"In accepting this Medal, I do so with a profound respect for the objectives of the Association: to keep ever refreshed the memory of a great man and master, to disseminate his inspiration, to join honor with responsibility in the service of our people. In honoring me you would recognize also my colleagues and the innumerable contributors to the science and practice of public health everywhere.

"For them as well as for myself I will treasure it as an expression of your approval and esteem, and, with the life of Dr. Sedgwick for an example, as a perennial commission to the service of humanity."

A.P.H.A. ADOPTS STATEMENT ON MEDICAL CARE IN A NATIONAL HEALTH PROGRAM

The Governing Council of the American Public Health Association at the 73rd Annual Meeting, recently concluded in New York City, gave extended consideration to the preliminary report on a national program for medical care published in the September, 1944, *Journal*, pages 984-988.

This report subsequent to its publication came before the Committee on Administrative Practice and was recommended with some editorial changes to the Governing Council for adoption. The discussion before the Governing Council brought out the statement of those in favor of the report and those opposed, and it was held over for 48

hours to permit full consideration and the preparation of a definitive report which then passed the Governing Council by a vote of 49 in favor, 14 against.

The report as adopted will appear in the December *American Journal of Public Health*. In the meantime persons desiring copies may obtain them by application to the Executive Secretary.

MILK LABORATORY SURVEY FORMS NOW AVAILABLE FROM A.P.H.A.

For everyone interested in plate counts of milk and milk products there is now available a handy form for checking the procedures used in making Standard plate counts against those recommended in the latest (eighth) edition of *Standard Methods for the Examination of Dairy Products*. Printed on both sides of a single sheet, the form covers the essential details of apparatus, preparation, and technics, which occupy 26 pages in *Standard Methods*.

The form was originally prepared by the U. S. Public Health Service for use in surveying milk laboratories throughout the country. It was considered so valuable by the *Standard Methods*

Committee that it has been published by the A.P.H.A. for sale and for free distribution with copies of the third reprinting of the eighth edition of *Standard Methods*. The price is \$1.00 for 50 copies, \$1.50 for 100 copies, or \$10.00 for 1,000 copies. Sample copies may be obtained without charge.

The form should be of value to administrators in improving the work of laboratories in their jurisdiction, to the bacteriologist and the technician as a guide in their work, and to those training new workers or teaching students in bacteriology, dairying, or public health.

DEATH OF MRS. KATHERINE ANDRUS

The members and Fellows of the Association who for years have dealt with the Central Office will learn with regret of the passing on September 23 of Mrs. Katherine P. Andrus who, since 1922, has been employed by the Association as Chief Clerk, and lately as Librarian. Her many years of faithful direction of the Book Service and other Association responsibilities were recognized by the Executive Board in a recent resolution.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Blinn A. Buell, M.D., Dept. of Health, Portsmouth, Va., Director of Health
Harold F. Dallas, M.D., 2205 Ryer Ave., New York, N. Y., Asst. Surgeon (R), U.S. P.H.S.
Homer L. Hiebert, M.D., 1517 Randolph, Topeka, Kan., Director, Div. of Tuberculosis Control, State Board of Health
Jack B. Porterfield, M.D., M.P.H., City Hall Annex, Richmond, Va., Director of Health, City Dept. of Health
Achilles L. Tynes, M.D., City Hall, Staunton, Va., City Health Officer

Laboratory Section

William Arcisz, Fisheries Technological Lab.,

College Park, Md., Bacteriologist, U. S. Fish and Wildlife Service

Dwight A. Joslyn, 18769 Saratoga Blvd., Birmingham, Mich., Research Bacteriologist, Parke, Davis & Co.

Elizabeth J. Rubenow, 61 Cleveland St., Orange, N. J., Asst. in Bacteriology, Brown Univ.

Alexander D. McClure, 20 Alberta Ave., Toronto, Ont., Can., Bacteriologist, Royal Canadian Air Force

Nathan Moskowitz, Second Service Command Lab., 90 Church St., New York, N. Y., Bacteriologist

Lt. Bernard Newman, Sn.C., Laboratory Officer, U. S. Army Hospital

Hugo W. Nilson, Ph.D., U. S. Fish and Wild-

life Service, College Park, Md., Technologist in Charge

Henry D. Piersma, Ph.D., Lederle Laboratories, Inc., Pearl River, N. Y., Director, Human Biological Div.

Lawrence W. Slancz, Ph.D., Dept. of Bact., University of New Hampshire, Durham, N. H., Assoc. Prof. of Bacteriology and Bacteriologist

Vital Statistics Section

Herbert I. Sauer, Tuberculosis Control Div., U. S. Public Health Service, Bethesda 14, Md., Medical Analyst

Engineering Section

Nolan O. Anders, P. O. Box 31, Gretna, La., Sanitary Officer, State Health Dept.

Capt. Robert E. Howell, Harvey Rd., Arden, Wilmington, Del., Sanitary Engineer, U. S. Army

A. J. Lambert, Box 144, Raton, N. M., Sanitarian, Colfax County Health Dept.

Raymond J. McCormick, 4172 Wilshire Blvd., Oakland, Calif., District Food and Sanitary Inspector, Dept. of Public Health

Capt. J. Harrison Quinn, Sn.C., Station Hospital, Nashville Army Air Center, Nashville, Tenn., Sanitary Officer, U. S. Army

Major Harvey R. Wilke, 108 E. Monroe Ave., Alexandria, Va., Supervisor, Water Purification Course, The Engineer School, Ft. Belvoir, Va.

Industrial Hygiene Section

Josephine DeBrincat, 320 Sherbrook St., Winnipeg, Man., Can., Public Health Supervisor and Industrial Nurse Consultant, Provincial Dept. of Health and Public Welfare

Grant S. Winn, Ph.D., Delco-Remy Div., General Motors Corp., Muncie, Ind., Director of Industrial Hygiene

Food and Nutrition Section

Mildred B. Barry, State Dept. of Health, Providence, R. I., Nutrition Consultant

Frederica L. Beinert, A.R.C., 529 S. Wabash Ave., Chicago 5, Ill., Director of Nutrition Service, American Red Cross, Chicago Chapter

Jane Dale, Ph.D., 76 State St., Albany, N. Y., Senior Nutritionist, State Dept. of Health

George T. Kensler, Ph.D., 500 Peshigo Court, Chicago, Ill., Bacteriologist, Kraft Cheese Co.

H. Josephine Simpson, 1790 Broadway, New York, N. Y., Editorial Asst., Public Health Committee of the Cup and Container Inst.

Public Health Education Section

Lucille C. Alexander, Virginia Cancer Foun-

dation, Inc., Murphy's Hotel, Richmond, Va., Educational Director and State Commander

Stella B. Applebaum, M.A., 25 W. 54th St., New York, N. Y., Staff Writer, *Parents Magazine*

Antonio Arias, 304 Flood St., Wichita Falls, Tex., Student, Univ. of Michigan

Roy H. Brooks, Sr., 320 S.W. 26th Rd., Miami 36, Fla., Director of Health Education, Miami Air Depot Air Service Command

Mary S. Buford, M.A., Box 361, Sand Springs, Okla., Student, Univ. of Michigan

Haskell W. Crammer, 512 N. James St., Rome, N. Y., Director, Health Education, Rome Army Air Service Command

Mollie C. Faison, 2851 Bedford Ave., Pittsburgh, Pa., Educational Coordinator, Tuberculosis League of Pittsburgh

Mary Elizabeth Gruwell, 2710 Echo Way, North Sacramento 15, Calif., Director, Industrial Health Education, Sacramento Air Service Command

Miriam P. Hart, 1719 East Washington St., Charleston, W. Va., Educational Consultant, Div. of Cancer Control, State Dept. of Health

Isaac N. Hayes, Robins Field, Ga., Director, Health Education, U. S. Army Air Base

William P. Hebert, 97 Smith Ave., Xenia, Ohio, Director, Health Education, Air Service Command

Augusta F. Jarman, University of Virginia Hospital, Charlottesville, Va., Exec. Secy., Cancer Foundation, Inc.

Bessie M. Keeney, 100 Mobile Drive, Fairhope, Ala., Director, Health Education, Mobile Air Service Command

R. E. Kiouss, Box 267, Clayton 5, Mo., Asst. Director, Sanitation Division, St. Louis County Health Dept.

Mary L. Lewis, 304 Glenwood Ave., Kinston, N. C., Public Health Educator, Lenoir County Health Dept.

Marion S. Nevers, M.S., 1372 Hancock St., Quincy, Mass., Exec. Secy., Norfolk County Health Assn.

Dr. Pedro B. de Araujo Penna, 145 rua Bambina, Rio de Janeiro, Brazil, S. A., Public Health Educator, National Department of Public Health

Roslyn A. Rosen, 7 Maple Place, Port Chester, N. Y., Student, Yalc Univ. School of Public Health

William A. Scholcs, M.S.P.H., P-77 Victory Rd., Washington Terracc, Ogden, Utah, Director of Health Education, Ogden Air Service Command

Rcece W. Scott, 123 Slocum Place, San Antonio, Tex., Director, Health Education, San Antonio Air Service Command

Ralph H. Snyder, 2616 N.W. 31st St., Oklahoma City 7, Okla., Director of Health Education, Oklahoma City Air Service Command
 Ruth M. Thompson, District Health Dept., Rockingham, N. C., Junior Public Health Educator, State Board of Health

Public Health Nursing Section

Myrtle Horton, 2614 W. 15th, Little Rock, Ark., Orthopedic Nursing Consultant, Arkansas Crippled Children's Division, State Dept. of Public Welfare
 Doris Kimmel, R.N., 303 W. Madison, Kirkwood, Mo., Field Supervisor, St. Louis County Health Dept.
 Marie Neuschaefer, R.N., 1705 Beaver Ave., Des Moines 10, Iowa, Director, Div. of Public Health Nursing, State Dept. of Health
 Theodora Sharrocks, R.N., 801 Riverside Drive, New York 32, N. Y., Administrative Educational Assistant, Visiting Nurse Service of New York
 Ruth E. Simonson, 501 West 120th St., New York 27, N. Y., Supervisor, Fordham Center, Visiting Nurse Service of New York
 Vernell A. Taylor, 126 Kirkman St., Lake Charles, La., Public Health Nurse, U.S. P.H.S., assigned to Louisiana-Calcasieu-Lake Charles Health Unit
 Rose Mary Wehner, R.N., 1104 Madison Ave., Edwardsville, Ill., Staff Nurse, State Dept. of Health

Epidemiology Section

Lt. Col. Phillip T. Knies, M.C., 514 19th St., N.W., Washington 6, D. C., Army Representative, Interdepartmental Quarantine Commission
 Paul J. Langan, State Health Dept., Charleston, W. Va., Field Epidemiologist, Bureau of Venereal Diseases
 Jonas E. Salk, M.D., School of Public Health, Univ. of Michigan, Ann Arbor, Mich., Research Associate in Epidemiology
 George Wolff, M.D., 103 University Ave., Glen Echo, Md., Research Fellow (Dazian Foundation), Div. of Statistical Research, Children's Bureau

School Health Section

Lester A. Kirkendal, Ph.D., U. S. Office of Education, Washington 25, D. C., Consultant in Social Hygiene for Schools

to diagnosis and oral surgery; some teaching experience. **PH-10-3**, The Medical Bureau (M. Burneice Larson, Director), Palmolive Building, Chicago, Ill.

NEWS FROM THE FIELD

A SUGGESTED "KEEP FIT" PROGRAM

The Joint Committee on Physical Fitness of the National Committee on Physical Fitness of the American Medical Association has requested the JOURNAL to reprint the attached suggested "Keep Fit" program for schools and colleges of America. Colonel Leonard G. Rowntree, MC, AUS, is Chairman of the Joint Committee which functions under the Federal Security Agency, Washington.

The schools and colleges of America have contributed greatly to the health and fitness of young Americans, but even greater effort is needed if their contribution is to attain a level commensurate with their opportunities and responsibilities to their pupils and their communities.

The following recommendations are proposed to help schools and colleges to define more clearly their responsibilities and to help them to attain these goals:

I. It is recommended that the following objectives be proposed to schools as minimum requirements of their programs in health and physical education—

1. Thorough physical examination of all children (a) on or before admission to school and at such regular intervals thereafter as may be deemed advisable; (b) on readmission to school following any major illness; (c) on teacher referral when the pupil's appearance, performance, or routine screening test records suggest failing health or defects. Whenever possible the parent or teacher should attend the examination of younger children.
2. Daily teacher inspection of all pupils for signs of deviation from normal health status.
3. Routine screening tests to discover defects of vision and hearing and failure to grow.
4. At least annual, preferably semiannual, dental attention for every pupil.

5. An annual inventory of the physical abilities of every pupil by teachers of physical education.

6. Suitable follow-up work to assure (a) the correction of correctible defects and the prevention of preventable conditions, and (b) the assignment of pupils to modified activities programs where this is needed.

7. The use of a cumulative record blank designed to follow the child throughout its school life and to record (a) the results of physical examinations, screening tests, and physical fitness inventories, and (b) the dates of major illnesses, immunizations, dental visits, and corrective measures taken.

8. Organized health instruction on all school levels and planned healthful living throughout the school experience. At elementary levels this may be undertaken as a part of larger projects. At secondary levels there is need, in addition, for instruction specifically devoted to this area. This should not be as a "rainy day" substitute for or otherwise at the expense of physical education. Irrespective of title or departmental affiliation such instruction must develop accurate knowledge, appropriate attitudes, and sound habits aimed to further individual and community health. This demands at least a semester course of organized health instruction on the junior high school level and a semester or year course on the senior high school level, equivalent in length and regulations to other standard courses, to be required of all students. These courses should be taught by adequately prepared teachers and for a requirement for graduation.

9. At the elementary level at least 40 minutes daily, exclusive of recess periods, devoted to planned physical education activities suited to the grade level involved.

10. At the secondary level (grades 7 to 12) a daily period of vigorous physical education. This period should be at least as long as the regulation class period, and be scheduled within the

school day. Pupils should be classified in respect to sex and grade, ability or special needs. Standards should be set for passing the course in all grades, and acceptable performance required for promotion and graduation.

11. Expert supervision and direction at local and state levels as for other fields. In some instances the training of a person may qualify him to supervise both health and physical education.
12. The strengthening and extending of advisory and consultative services of the U. S. Office of Education in these areas.

Further school efforts to improve the physical fitness of youth could wisely be directed toward (1) extension of health inventory and correction of defects in the preschool years; (2) insuring sound mental health; (3) improvement of child nutrition through the provision of adequate school lunches; (4) provision of camping and other extended school services contributing to health; (5) systematic coöperation with all community health efforts such as tuberculosis case finding, venereal disease control, and maternal and child health clinics.

II. It is recommended that teacher training institutions be urged to include in their program for training teachers, instruction and practice in the daily observation of children for the purposes of detecting signs indicating possible deviations from normal health and development.

III. It is recommended that professional training institutions be urged to revise if necessary their programs for the training of teachers of health and physical education and of recreation leaders to give special consideration to promotion of health and physical fitness.

IV. It is recommended that teacher training institutions be urged to give some training in the conduct of physical fitness activities to all prospective teachers.

V. It is recommended that plans be perfected for giving special consideration to post-war planning of school facilities toward better provision for coöordinated school and community health and physical education programs and for extended community use of school facilities.

ARMY TO USE INFLUENZA VACCINE

According to a recent announcement of the War Department, plans are under way for a vaccine to combat the spread of influenza should the disease occur in epidemic form. The Commission on Influenza under the Army Epidemiological Board, has stated that the vaccine will not be administered routinely but will be given only on definite indication of the threat of influenza and only to personnel under risk of exposure to the disease. The Commission on Influenza, of which Dr. Thomas Francis, Jr., Professor of Epidemiology at the University of Michigan School of Public Health, is the director, carried out in 1943 a control clinical trial of the prophylactic efficacy against epidemic influenza of a concentrated vaccine containing the killed influenza viruses Types A and B. In coöperation with a number of civilian and military agencies an extensive investigation was carried out showing that there was a reduction of about 75 per cent in the incidence of influenza among the vaccinated as compared with the unvaccinated controls. It was also established that the illness of vaccinated persons was milder and shorter. The vaccine which was used was developed by Dr. Francis and Dr. Jonas E. Salk and their associates.

EFFECTIVENESS OF ULTRA-VIOLET DISINFECTING LAMPS IN SCHOOLS

A report has recently been released by the Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association bearing on the question as to whether the installation of ultra-violet lamps in schoolrooms for sterilization of the air is warranted. According to this report, the Council on Physical Therapy of the American Medical Association does not accept ultra-violet lamps for which claims are made that they will prevent cross-infection in schoolrooms or will disin-

fect solids. This Council acceptance of ultra-violet disinfecting lamps is limited to installations in hospital nurseries, hospital wards, and operating rooms.

"... satisfactory evidence is not available to warrant acceptance of ultra-violet lamps for disinfecting solids. To kill a microorganism a direct hit by ultra-violet rays of sufficient intensity is required. This is difficult to accomplish on the edge of a drinking cup, for example, also in a liquid containing suspended matter or in air laden with dust particles that shield the organism. Ultra-violet radiation cannot penetrate deeply and hence may be absorbed by finger marks, saliva, cosmetics, or other foreign matter on a drinking cup. In view of the present available evidence, ultra-violet radiation appears to be an uncertain means of sterilizing solid objects (drinking cups, combs, brushes, shaving utensils, toilet seats, and shoes) even if irradiation of the whole surface is possible. Ultra-violet lamps are not accepted for disinfecting air in schools, waiting rooms, public gathering places, and large halls. The evidence now available does not indicate that the incidence of colds can be reduced by the installation of ultra-violet lamps and by the irradiation of an enclosure occupied by people.

"It must be remembered that injurious physiologic effects may arise from prolonged ultra-violet irradiation of a person. Overdoses of ultra-violet rays will produce conjunctivitis and a serious erythema. Since the occupants of the room must be shielded from the rays, the space containing the highest concentration of infectious microorganisms is not irradiated. Those droplets laden with bacteria and emitted by the infected person are distributed so that they are freely inhaled by a recipient long before the natural or artificial flow of air will carry the droplets to the irradiated spaces. It follows, therefore, that disinfecting lamps are of little or no value in preventing cross-infection in schoolrooms."

USING RESULTS OF HEALTH EVALUATION

The Birmingham-Jefferson County Public Health Committee of the Birmingham Chamber of Commerce (Alabama) has demonstrated how to use the results of a health evaluation effectively. Following the submission of a schedule to the American Public Health Association for the National Health Honor Roll, a most attractive eight page pamphlet has been issued which repro-

duces the critical comments from the American Public Health Association in interpreting the local schedule. The Health Officer, Dr. George A. Denison, writes to the American Public Health Association:

"The 1943 evaluation study has been most helpful to this department, both in pointing out weaknesses and need for strengthening certain fields and in developing better public relations and understanding."

But better yet the Health Committee includes in the pamphlet what has been done in correcting weak situations and what is going to be done in the future. There is every indication that Birmingham and Jefferson County are serious about public health protection and mean to build a strong program.

ADVERTISING AGENCY SURVEYS COLDS

Dr. Travis P. Burroughs, Health Officer of Portland, Me., reports that information has been solicited by telephone and personal visit from the residents of Portland who were asked to supply the record of recent colds to the "Public Health Survey Research Department."

According to Dr. Burroughs, this survey is under the auspices of Morse International, Inc., Advertising, 122 East 42nd Street, New York, N. Y., of which M. F. House is President. The solicitors are alleged to claim representing the Health Department in soliciting the information.

THE AMERICAN CANCER SOCIETY, INCORPORATED

Announcement has been made by the American Society for the Control of Cancer, Incorporated, New York, N. Y., that the name of this organization is now changed to the American Cancer Society, Inc. In the future the society's lay organization, the Women's Field Army, will be known as the Field Army, and men as well as women will

be identified with this work. J. Louis Neff has become Executive Director, and George B. Larson, formerly assistant secretary of the Wisconsin State Medical Society, Madison, has become director of publicity and public relations. According to the society's announcement, the society plans to expand and to extend its efforts not only to educate the public but to obtain from the public funds for cancer research, diagnosis, treatment and education.

AMERICAN RED CROSS APPOINTS MEDICAL COMMITTEE

Basil O'Connor, Chairman of the Central Committee, American Red Cross, has announced the appointment of a Special Medical and Health Committee to survey current Red Cross operations of a medical and health character and to recommend plans for the post-war period. On the committee the following members have been appointed:

- Dr. Lewis H. Weed, *Chairman*, Washington, D. C., Division of Medical Sciences, National Research Council
- Dr. Felix J. Underwood, *Vice Chairman*, Jackson, Miss.
- Dr. George Baehr, New York, Director of Clinical Research, Mt. Sinai Hospital
- Dr. Wilburt C. Davison, Durham, N. C., Dean and Professor of Pediatrics, Duke University, School of Medicine
- Dr. Morris Fishbein, Chicago, Editor *Journal of the American Medical Association*
- Dr. Alan Gregg, New York, Director of Medical Sciences, Rockefeller Foundation
- Major Gen. Norman T. Kirk, Washington, D. C., Surgeon General, U. S. Army
- Dr. Frank H. Lahey, Boston, Lahey Clinic
- Dr. Roger I. Lee, Boston, President elect, American Medical Association
- Vice Admiral Ross T. McIntire, Washington, D. C., Surgeon General U. S. Navy
- Dr. Thomas Parran, Washington, D. C., Surgeon General U. S. Public Health Service

Dr. Henry R. Viets, Boston, will act as Secretary of the committee.

In announcing the committee, Mr. O'Connor said:

Medical and health problems touch virtu-

ally every aspect of Red Cross activities, whether in terms of disaster relief, nursing, accident prevention, nutrition, or blood donations. Because of this vital relationship to the general Red Cross program, I have asked 11 prominent medical and health experts to serve as a special committee to survey what we are doing currently, analyze the results achieved, and give me a blueprint of possible Red Cross Activities in these fields in the post-war period. The group appointed was chosen because of their familiarity with operations of the American Red Cross in the medical and health fields.

PERSONALS

Central States

WILLIAM A. CORCORAN, M.D., has been appointed Health Officer of Ishpeming, Mich., succeeding NEAL J. McCANN, M.D.

DOUGLAS S. FRYER, M.D., D.P.H.,† resigned August 11 as Assistant Director of the Bureau of Local Health Services, Michigan Department of Health, Lansing, Mich., to join the Wyeth Laboratories, Philadelphia, Pa.

FRED J. WAMPLER, M.D.; DR.P.H.,* Professor of Preventive Medicine at the Medical College of Virginia, Richmond, Va., has resigned to accept a position as Medical Director with the Rustless Iron & Steel Corporation, Baltimore, Md., effective October 1.

Western States

THOMAS H. BIGGS, M.D., has been appointed Health Officer of Kelso, Wash., in addition to his work as Health Officer of Cowlitz County.

JOHN H. FOUNTAIN, M.D., M.P.H., has been appointed Medical Director of the Morningside Tuberculosis Hospital, King County, Wash. Dr. Fountain is a graduate of Georgetown University in medicine and of the Harvard School of Public Health. He has served recently as Health Officer of Weld County, Colo., and as Health Officer of Denver.

EMIL E. PALMQUIST, M.D.,† Seattle, Wash., Health Officer of King County, has been elected President of the Washington State Social Hygiene Association.

Foreign

JOSEPH S. MAXWELL, M.D., formerly missionary to Ethiopia, has been appointed physician at Wheaton College, Ill.

* Fellow A.P.H.A.

† Member, A.P.H.A.

Deaths

PROFESSOR ISRAEL JACOB KLIGLER,* occupant of the Jacob Epstein Chair of Bacteriology and Hygiene at Hebrew University, Palestine, since 1926, died on September 23.

MARY McCORMICK, R.N., of the State Department of Health, Albany, N. Y., died on September 2.

SENIOR SURGEON LIEUEN M. ROGERS, M.D., of the U. S. Public Health Service, Fort Worth, Tex., died of a heart attack on September 7.

* Fellow A.P.H.A.

† Member A.P.H.A.

CONFERENCES AND DATES

American Society of Heating and Ventilating Engineers—51st Annual Meeting. Hotel Statler, Boston, Mass. January 22-24, 1945.

American Water Works Association—New Jersey Section—Hotel Madison, Atlantic City, N. J. November 2-4.

Four States Section—Benjamin Franklin Hotel, Philadelphia, Pa. November 8-10.

Virginia Section—John Marshall Hotel, Richmond. November 14-15.

South Dakota Water and Sewage Works Conference. Lincoln Hotel, Watertown, S. D. November 14-15.

Florida Section—Suwanee Hotel, St. Petersburg, Fla. November 16-18.

New York Section—Mid-winter Luncheon Meeting, Pennsylvania Hotel, New York, N. Y. January 17, 1945.

Annual Seminar on Reading Disabilities. Pennsylvania State College, State College, Pa. January 29-February 2, 1945.

Association of Military Surgeons of the United States. Hotel Pennsylvania, New York, N. Y. November 2-4.

Civil Service Assembly—Conference on Public Personnel Administration. Chicago, Ill. November 1-3.

Florida Public Health Association. Gainesville, Fla. December 4-6.

Institute of Medicine of Chicago—Postgraduate Assembly on Nervous and Mental Diseases and War. Palmer House, Chicago, Ill. November 1-2.

Michigan Public Health Association. Grand Rapids, Mich. November 1-3.

National Chemical Exposition—Sponsored by the Chicago Section of the American Chemical Society. The Coliseum, Chicago, Ill. November 15-19.

National Committee for Mental Hygiene—35th Annual Meeting. Hotel Pennsylvania, New York, N. Y. November 8-9.

New Mexico Public Health Association. Santa Fe, N. M. November 8-11.

New York State Association of Public Health Laboratories—Midyear Meeting. State Laboratory, Albany, N. Y. November 17.

U. S. Public Health Service—National Conference on Post-war Venereal Disease Control. St. Louis, Mo. November 9-11.

HOW TO REMOVE

MILK DEPOSITS

On the farm with DICOLOID

A dry, concentrated product, Dicoloid is readily applied in paste form with a wet brush. Penetrates, dissolves and suspends milkstone deposits through its powerful wetting and cleaning action . . . its casein and mineral dissolving properties. Safe to hands or utensils. Agricultural Experiment Stations have shown that milkstone is often the cause of high bacteria counts in milk.

In the plant with DILAC

Diversey Dilac has been specially developed to quickly and effectively remove the stubborn contamination that forms daily on short-time, high temperature pasteurizing units. . . . Softens and dissolves milkstone so it can be completely removed with a minimum of time, labor and material. Write for technical bulletin "Milkstone Control." The Diversey Corporation, 53 W. Jackson Blvd., Chicago 4.

Content and Administration of a Medical Care Program

A Brief of the Report on Medical Care in a
National Health Program *

JOSEPH W. MOUNTIN, M.D., F.A.P.H.A.

Assistant Surgeon General, U. S. Public Health Service, Washington, D. C.

BEFORE a professional body such as the American Public Health Association, there is little purpose in belaboring the point that the great unsolved problem in public health is one of making available to every American citizen the full benefits of good medical care. The very fact that this problem has already taken on the status of a political issue is a more convincing indication of its importance than any argument or body of statistics that could be adduced. The intemperate support of limited remedial measures by partisan groups, as well as the blind opposition to any change in the *status quo* encountered from other sources, clearly indicate the need for responsible agencies to give technical direction to the public movement for better medical care. The American Public Health Association should be peculiarly fitted

to give such direction, since its members are familiar with the intimate character of medical service and can see the problem from the point of view of both those who receive and those who provide health services.

Mindful of the urgency in this matter, the Committee on Administrative Practice at its meeting in November, 1943, directed its Subcommittee on Medical Care to draft a set of principles which would describe the content of a suitable medical care program and methods of administration. Inasmuch as a great wealth of material had already been accumulated through basic studies and as a result of practical experience in the operation of limited medical care programs, it was decided that the first job for the subcommittee to undertake should be to analyze these findings rather than engage on additional research studies. The subcommittee was fortunate in having as members individuals who had participated in former studies, others who

* Presented before the American Public Health Association at the Seventy-third Annual Meeting in New York, N. Y., October 4, 1944.

were familiar with the experience gained in various organized methods for distributing medical care, and still others responsible for medical care programs now in operation—in brief, its composition included both students of the problem and practical administrators.

The subcommittee met several times during the past twelve months. After exploring in detail many of the problems involved in the design of a national medical care program, the group felt that its thinking had reached the stage at which a statement of principles could be formulated. A preliminary report setting forth these principles has been released. It was published in the September, 1944, issue of the *American Journal of Public Health*, with the thought that the entire membership of the Association might have ample opportunity to study the proposals in advance of formal action. After some modification, this report was accepted by the Committee on Administrative Practice and passed on to the Governing Council with suggestion that it be considered as an expression of Association policy. There follows a brief summary of the report, together with a few of the underlying considerations.

The objective of a national medical care program should be to make available to the entire population, regardless of the financial means of the individual, the family, or the community, all essential medical services. Such services must be of high standard and rendered under conditions acceptable to the public and the professions concerned. In scope they should include hospital care, the services of physicians, laboratory and diagnostic services, nursing care, essential dental services, and prescribed drugs. Because of inadequacies of personnel and facilities, all of these measures cannot be provided immediately to the whole population, but their complete development within

ten years may be taken as a goal. Regardless of temporary shortcomings, a beginning should be made now in the provision of services to the extent that available personnel, facilities, and administrative technics make possible. Later, but as rapidly as possible, the program should be expanded to the intended scope.

An achievement of the objectives of a national medical care program, the subcommittee thought, would require simultaneous attack on five main fronts; namely, distribution of costs, development of administrative organization to provide the service, training of personnel, construction of facilities, and improvement of knowledge.

The basic problem in providing more and better medical care for persons of all circumstances is that of distributing costs over the entire population in proportion to ability to pay. Already the phenomenal success of non-profit voluntary insurance against hospitalization costs makes it quite apparent that the people desire a convenient way of paying for medical care, and especially a way that will give protection against the risk of heavy bills. Despite such achievements, there is ample reason for believing that voluntary insurance unaided will not be able to include the whole population for all of its medical needs.

The subcommittee therefore came to the conclusion that health services must be financed by compulsory social insurance contributions supplemented by general taxation, or by general taxation alone. Financing through social insurance contribution alone might result in the exclusion of farmers or self-employed persons, or still other occupational groups, who need the advantages of prepayment as much as industrial and commercial employees. Certain of the long-term disabling conditions, such as mental disorders and tuberculosis, had better be financed for the present at least, as

they now are, out of general revenue separate from the provisions for general illness.

The subcommittee was unwilling to compromise the principle that service should be of high quality and available to all persons regardless of economic circumstances or geographic location. It also recognized the desirability of decentralized operation, with participation by state and local authorities. Because of the great mobility of our population and the wide variation in economic resources among the several states and their political subdivisions, an unrelated series of state or local plans cannot assure a suitable service national in scope. Only the federal government through its broad powers of taxation can compensate for those differences in income which exist among individuals and among the lesser units of government.

After the fund has been collected through social insurance or taxation, arrangements must be made whereby the institutions and professions rendering service may be paid for their efforts. The great bulk of service in this country today is performed by voluntary hospitals and private practitioners; they need to be brought into the scheme. Methods of paying hospitals for their services have been developed under extensive voluntary insurance plans; these methods can be readily adapted to the requirements of a national health program. The problem of compensation for professional service is more complex. Inasmuch as fee-for-service has been a tradition, this with suitable controls may have to be accepted as one of the methods; however, the inherent defects in fee-for-service should be faced, and it should be recognized from the beginning that unsatisfactory experience may in time force more extensive utilization of other methods.

The subcommittee believes that the

principle of free choice must be preserved for the public, the professions, and the institutions; namely, that patients shall be at liberty to select their physicians from among all who participate, subject to acceptance by the physicians; and to select their hospitals, subject to the practices and the staff arrangements of the hospitals; and that all qualified physicians and hospitals shall be eligible to participate in the program. This principle should apply to group as well as to individual action.

At the present time public medical care functions are being discharged through a host of agencies at all levels of government. The effective operation of a national program requires that at each level of government—federal, state, and local—administration, or the supervision of administration, should be by a single responsible agency. Because of their strategic position in the framework of government, their record of successful administrative experience, and their interest in prevention as well as cure of disease, health agencies are believed best fitted to discharge the responsibilities incident to administration of a nation-wide medical care program. However, any agency that expects to carry major responsibilities in a program of such magnitude and complexity should begin preparing itself now for the position it intends to occupy. When the public comes to consider where administrative responsibilities for a national health service shall be lodged, it will be influenced in large measure by the readiness for such duties displayed by the agency, by the initiative taken in fitting itself for the task, and by the eagerness shown in wanting to accept these responsibilities.

Perhaps of more interest to the members of this Association than the operation of a plan at the national level is its management locally. It is here where the program functions in relation to the needs of the people and where

the true measure of satisfaction is determined. Irrespective of whether the national program be a federal scheme or federally aided state schemes, it must operate through units of control that are in direct contact with the people who receive the service, and with the facilities and personnel through which the service is delivered.

The subcommittee gave thought to the proper size of jurisdiction for local service and to the relative advantages and disadvantages of state administrative districts as compared with districts composed of one or more existing political units. If, as the subcommittee believes, local health agencies should take a prominent part in the administration of medical care, it is difficult to escape the conclusion that material modification in the boundaries of local health jurisdictions must be effected in most, if not all, of the states. For the most part health agencies are built upon a foundation of law enforcement. Consequently, health jurisdictions conform, in the main, to local political boundaries. Many of these areas are too limited in population for efficient administration and their resources are so limited as to make it difficult for them to make any substantial contribution to a program, such as medical care, which involves large sums of money. Furthermore, neither hospitals nor physicians have been accustomed to draw their clientele from within the confines of existing local political subdivisions. In other words, medical service must continue to follow the natural lines of trade areas. Health officers are rapidly coming to the belief that public health jurisdictions also must be reshaped in similar fashion. Whether these areas be made administrative districts of the state, or become new political entities with considerable degree of local autonomy, must be left for determination by the state and local authorities concerned. In reality a decision either way is not of great im-

portance from the standpoint of developing a suitable framework for medical service.

Under an acceptable plan of medical care the hospital must occupy a central position. In addition to providing beds for the more serious cases of illness, its facilities should be generally available for diagnosis and treatment of ambulatory patients and for appraisals of physical status. Before these purposes can be accomplished, it will be necessary to construct additional hospital accommodations in many rural areas where such facilities are nonexistent or wholly inadequate. Even in the larger centers of population a high proportion of present hospitals are in need of extensive alteration, or replacement by more modern structures.

When bringing the total bed capacity of hospitals throughout the country up to actual requirements, a concerted effort should be made to replace the individual and haphazard arrangement that has characterized hospital evolution to date by a planned development under national and state guidance. The scope of service in existing and proposed hospitals should be arranged so as to meet the needs of the localities in which they are situated and fit into both the state and the regional scheme of hospitalization. Under such a plan the modern medical center as well as the outpost first aid station will have its place.

Closely related to the location of hospitals is the placement of physicians and other medical personnel. A hospital without a competent medical staff is of questionable value, but on the other hand experience has shown repeatedly that a community cannot expect to attract and retain qualified physicians in sufficient numbers unless opportunities for hospital practice are afforded. A large part of the maldistribution of physicians could be corrected in short order if advantage

should be taken of the unusual opportunities that will attend demobilization of the armed forces for placing physicians where they are most needed. The presence of hospital facilities, together with the assurance that funds are available for the payment of medical bills, will go a long way toward effecting a permanent distribution of physicians in proportion to the population. For the more remote and sparsely settled areas some measure of direct aid in addition to the foregoing broad provisions may be necessary. Such instances should not be numerous and neither should the costs entailed be burdensome.

Under an expanded medical care program shortages of personnel no doubt will be experienced for most categories of service. This is likely to occur especially if the present pattern of practice is carried over into a national program. Dentistry perhaps represents the most critical situation. While this general subject of personnel requirements and methods for meeting probable needs deserves further study, the subcommittee pursued the matter far enough to be impressed with wastages of resources which normally occur. The average physician in private practice does not reach his maximum performance until age 40 and, after a period of about 5 years, a falling-off in output begins. The time of nurses consumed in maid and clerical services has been a subject of study and unfavorable comment for years. Now it would appear that many of the operations done by dentists could be assigned to persons of less training than that prescribed for graduation from dental schools. Much more work needs to be done in the way of job analyses before precise statements can be made regarding the extent to which subsidiary personnel can be used to lessen the demands for those in higher educational brackets. Likewise, a great amount of thought needs to be given to the training of auxiliary per-

sonnel themselves, and their certification for prescribed types of work. At present this whole matter is in a chaotic state. Until the entire subject of auxiliary workers has been fully explored it will be difficult to make calculations as to the needs for personnel with more extensive preparation.

Of all the groups that contribute to medical service the basic professional education of physicians seems to have been fairly well stabilized at sufficiently high level to assure good quality of medical graduates. If used to full capacity the present number of medical schools, or possibly with moderate increase, should be able to satisfy the normal needs for physicians by the population of the continental United States. The great unsolved problem in medical education is that of keeping physicians abreast of scientific and technical advances subsequent to completion of their formal education. This deficiency is especially apparent among physicians who, because of location or lack of hospital connections, become isolated from their fellow practitioners. The mere provision of additional hospitals and clinic facilities alone will not solve this problem. A continued educational influence must be infused into the system. This influence should emanate from teaching nuclei which may be located in medical schools or medical centers to which satellite institutions of the surrounding areas are related. In addition, individual physicians must be encouraged to pursue specialized courses so that the particular needs of each locality may be properly satisfied. Within reasonable limits these and other measures necessary for maintaining quality of service should be regarded as appropriate for public support, but should not be charges against the medical care fund proper.

From the very outset there should be a frank recognition of the fact that

any medical care program is certain to deteriorate unless research goes hand in hand with the provision of service. Hence the support of research, like the support of personnel training, must be accepted as a legitimate and necessary item in the over-all cost of medical care. When selecting topics for basic research, it would seem appropriate that primary consideration be given to conditions such as mental disorders and chronic disabling disease of advancing years, which tend to overburden any comprehensive program of medical care. In the normal course of operating a medical care program endless opportunities will arise for improving service and reducing costs; such matters constitute appropriate subjects for the administrative type of research. There will

also be need for the pilot-plant type of installation in which new procedures are tested and perfected prior to full-scale application.

In the foregoing discussion an attempt has been made to set out the circumstances which prompted the preparation of the report of the Subcommittee on Medical Care, the subject matter considered, and the factors which determined the conclusions. Each of the problems under discussion has many facets. Papers that follow in this symposium represent attempts to describe in more detail the underlying factors which have precipitated out medical care as a national issue, and the corrective measures that seem applicable, together with appropriate methods of administration.

Content and Administration of a Medical Care Program

Unmet Health Needs *

I. S. FALK, PH.D., F.A.P.H.A.

*Director, Bureau of Research and Statistics, Social Security Board,
Washington, D. C.*

IT is the history and the proud tradition of modern public health that it is foresighted. It has attained its present high level not through accident—though unforeseen developments have played a part—but primarily through careful study and planned action.

Public health progress has depended on periodic review of accomplishments, planning to meet unmet needs, experimentation, concurrent evaluation of activities, and repetition of this time-tested and productive sequence.

This basic method of the public health campaign is being constantly applied, operating for the most part in quiet ways—without drama or crisis. Occasionally it is applied in more unusual fashion—as when some event or circumstance provides special reason to take stock or to meet new needs. An epidemic or some other catastrophe has sometimes precipitated action, so that something good and useful for the welfare of society was fertilized by the ashes of tragedy.

Today, American public health is confronted with unusual circumstance. The times demand unusual action—to make a special appraisal of unmet needs, to recognize the barriers to health progress, and to plan courageously and adequately how to level

those barriers and how to meet those needs.

It is conceivable that, in a world in flames and disorder, we shall make a transition from war to peace without serious disruptions and by smooth and gradual stages; and it is possible that public health practice in the United States will pursue the even tenor of its way. But it is also possible that our society will be wracked by social and economic strains, and that the machinery and the practices of our health services will be deeply affected.

For a decade and more we have been hearing with increasing insistence that people have learned of the new and enlarged possibilities for health and that they demand a share in these opportunities. This demand has now swelled to large proportions. We of the public health profession should not fear and evade it; we should welcome it. And we should also note that the new public demand for health service is not so much in the traditional patterns of public health, with its primary concern for premature mortality, as in the newer patterns of social security, with its emphasis on assurance of needed medical and hospital care, and protection against the suffering and the economic burdens of sickness, disability, and dependency.

We have given some thought and attention to this subject in our Association. It is timely that we give it more.

* Presented before the American Public Health Association at the Seventy-third Annual Meeting in New York, N. Y., October 4, 1944.

PERSISTENT MORTALITY AND
MORBIDITY

For some generations, public health administration leaned primarily on death rates to measure need, and on changes in these rates to measure accomplishment. The technical validity of that practice rested upon two assumptions—both more generally implicit than explicit—first, that public health was chiefly concerned with preventing the occurrence of preventable fatal diseases; and, second, because fatality rates were relatively constant, that changes in death rates reflected trends in the incidence of both illness and death. In the years when the greatest concern was with preventable infectious diseases, these assumptions were substantially valid; mortality rates were useful as primary indexes of health, and reductions in those rates were indexes of progress in the public health. But time marched on.

It is a striking fact—yet still widely unrecognized—that most sickness and most deaths in our times result from causes that we cannot control in the sense of preventing their occurrence. One has only to scan a list of the principal causes of either morbidity or mortality to see this plain truth.

We take great pride in the reductions that have been effected in the death rates—from about 17 or 18 deaths per 1,000 at the beginning of the century to about 11 per 1,000 in 1940. But we often forget that about 70 per cent of that reduction had already occurred by 1920, and practically 100 per cent by 1930. Such further reductions as have occurred among some causes and in some age groups are offset by increases elsewhere. Or, to take the matter in closer perspective, the prototypes of disease controllable by public health methods are typhoid and paratyphoid fevers, diphtheria, diarrhea and enteritis, measles, scarlet fever, whooping cough, and tuberculosis. Their ag-

gregate death rates declined by about 83 per cent from 1900 to 1940; but about 56 per cent of that decline had already occurred by 1920, and about 84 per cent by 1930. It is true that much yet remains to be done in controlling these infections and we should press home their more complete control or eradication. We need to remind ourselves, however, that this group of preventable deaths was directly responsible in the last census year for only 1 death in 22. All other causes of death declined by less than 25 per cent in the first 40 years of this century; some among them show increasing death rates. We should be getting on with the job of tackling them as prevalent causes of disease and death.

The most common plagues that afflict us now are not preventable as causes of sickness or premature death by the traditional public health methods of community-wide control, or they are not preventable at all with present knowledge, methods, or skills. And, because of their concentration in the higher ages, the prospective aging of the population will increase the relative prevalence of these non-preventable illnesses.

MEDICAL CARE AS A PREVENTIVE SERVICE

Yet—if I may speak critically—we still act by patterns of public health practice as though preventable infectious diseases were our greatest problems, while we concern ourselves relatively little with heart disease, pneumonia, rheumatism, and other diseases which are vastly more prevalent and cause far more suffering and damage to human resources. These diseases which we cannot wholly prevent need early detection and accurate diagnosis; the patients need prompt, comprehensive, and continued care—home, office, clinic, hospital, laboratory, and other services—from the physician, dentist, nurse, laboratory expert or

pharmacist, and the host of others who stand behind them and support them. With these services public health has been relatively little concerned, because it has regarded medical care for the individual as being generally outside its field. In the past ten or fifteen years, the generously given advice "go see your family doctor" has been a feeble and futile substitute for a useful and effective program to assure the actual availability of services to those who need them.

This does not mean that public health practice has followed a consistent pattern of avoiding medical services, witness the long history of medical intervention by public health agencies in the case of tuberculosis and the more recent activity in respect to mental diseases, cancer, the venereal diseases, and the pneumonias. A few other examples, of uncertain generality, might be cited. Yet it still would be correct to say that public health practice has done and is doing little—very little, indeed, by comparison with the size of the need and the opportunity for useful service—about the commonest and most important causes of morbidity and disability; it still largely neglects to assure the availability of those services that would alleviate sickness and suffering where it admittedly cannot prevent the onset of disease.

In the past two or three decades, public health practice has shown a strong tendency to shun individual services. In the same periods, the public has become increasingly insistent in its demand for more and better individual services. These diverging trends explain in considerable part the continuing inadequate financial support of local public health activities. Lacking the public support that comes from the direct provision of personal service, public health officers have generally had an uphill fight in defending increased budgets for services that are for the

most part vague and impersonal to the taxpayer.

Everywhere about us are people who have learned the new wonders that science holds for health. Their demand for services that will heal the sick is not to be met by new promises to prevent other illnesses that have not yet occurred. This demand has now reached such proportions that it cannot be much longer denied or ignored, especially because millions of people have learned there are ways of meeting the problems of costs that restrict the availability of needed services. There is now substantial agreement, nation-wide, that action will soon be taken. The public health professions cannot stand aloof.

The paramount issue before public health leadership in the United States concerns the place of medical services within the framework of public health practice. We are all agreed that the first function of public health is to prevent. But must prevention deal only with the initial occurrence or onset of a disease? Or shall it also mean that disease which cannot be prevented shall be recognized early in its course and treated promptly and effectively in order that human suffering shall be avoided; that the period of illness shall be shortened; that the course of the illness shall be moderated, shall not go on to more serious sickness, and shall not lead to further scarring and injury; that illness shall not lead to disability; that disability shall not be more prevalent than it has to be?

The practical import of these contentions is that medical care must be regarded as an integral part of a broad program of public health, one that embraces not only traditional community-wide services and special provisions already developed for particular diseases or special population groups, but also general diagnostic and treatment services for all members of the community. This involves the availability of med-

ical care of high quality, in early as well as late stages of disease, and ready access to the needed services throughout the entire period in which they are required. It also involves coördination of the diagnostic and treatment services with the more strictly preventive services—statistical, sanitary, laboratory, policing, educational, and administrative—and with the services for rehabilitation of the handicapped and the disabled. Also, having regard for the interrelations between poverty, disease, and dependency, the broad health program involves coördination with provisions for maintenance of income and for education, good nutrition, healthful housing, and other social purposes that are widely accepted as being essential or important to health.

The first unmet health need today is the design of a new public health program, adequate in both scope and content for our times.

SOME SPECIFIC NEEDS

If we are to enter upon a program of positive health and medical care for the people of this country, we must come to closer grips with the needs that are to be met. While taking into account the problems resulting from the war, we should hold them in perspective by reference to pre-war circumstances and post-war outlooks.

How much illness is there ordinarily in our population? No one knows exactly, especially because the amount of illness found in any group depends upon the intensity of the search made to discover it. Improved and enlarged reporting of morbidity is one of the important unmet needs. The deficiency has been partly overcome through special studies. By carefully combining the evidence from extensive and intensive surveys, it appears that on an average day at least 7 million persons are unable to carry on their usual pursuits because of disabling illness. Un-

der conditions of careful reporting, the incidence of recognized illness is about 1 case per person a year, including in this figure both disabling and non-disabling illness, but omitting most minor illnesses and undiagnosed conditions. About 1 person in 5 suffers from a chronic disease or a major physical defect which needs medical attention. Many of these conditions are caused by the so-called "degenerative diseases" which so commonly prevail in middle age and in the more advanced years, and which usually need protracted and expensive care.

Whenever representative groups in our population are carefully examined, with the physician's skill supplemented by laboratory tests, vast amounts of neglected ill health and physical defect are uncovered. The large proportion of presumably healthy young men who were rejected for general military service because of defects and handicapping conditions is now well known; it came as a surprise only to those impressed by progress in the death rates and in the average expectation of living measured at birth or in the early years of life, and to those uninformed of the large number of people who do not receive the medical services they need.

There are many reasons why people who need medical care do not always receive it. The underlying causes are primarily economic. Medical care costs money. Illness and its costs are unpredictable for the individual, though they can be forecast with reasonable accuracy for the large group. The annual burden of sickness costs falls mainly upon a small proportion of the population, and usually comes unexpectedly upon the individual or family. In planning for better medical care, the most important characteristic of medical costs which must be surmounted is their uneven distribution among individuals and families.

Low-income families have more than

average amounts of illness, larger and more frequent need for care, and they spend a proportionately larger share of their incomes on sickness, yet they receive far less medical service than the well-to-do and the wealthy. For many, the costs constitute a barrier which prevents the receipt of needed care or any care at all. Below the level of the well-to-do, the percentage of illness which is without medical attendance rises steadily as income declines. Inadequacy of care and lack of care are especially widespread among the millions who live in rural areas. Those who are most familiar with rural conditions assure us that "modern medicine as we boast of it today is an urban phenomenon." And Negroes are generally worse off than white persons. It is easy to recognize how the vicious circle runs—illness causes poverty; poverty is associated with unattended and neglected illness. Which is cause and how much is effect cannot always be disentangled. We can be sure, however, that the circle needs to be broken from outside its perimeter.

POVERTY AND MEDICAL NEEDS

These generalized and summarized statements about sickness and medical neglect may be unimpressive to those not accustomed to think in statistical terms. If time permitted, the facts could be made more specific by referring not to all sickness or all kinds of medical care, but to tuberculosis, cancer, pregnancy, heart disease, pneumonia and other specific causes of illness, or to medical, dental, nursing, hospital or laboratory services.

It is so frequently repeated that the poor and the rich get good medical care, or the best medical care, that many have come to believe it. No doubt, one can see here in New York City, where we are meeting, numerous examples to illustrate receipt of the highest grade of care by the indigent poor—given by

some of the ablest physicians in the city, in well-equipped hospitals and clinics operating at high levels of skill and efficiency. But who among us does not know that very few large cities and fewer smaller cities and almost no rural areas have made the provisions for the medical care of the poor that are to be found here? Those particular individuals among the poor so fortunate as to be served by leading clinicians in "free" clinics and "free" hospital beds may be receiving service of high quality. But this does not alter the fact—attested by scores of health or welfare studies—that in most urban areas and in nearly all rural areas poverty and lack of medical care go along together. It was true three-quarters of a century ago when this Association was founded; it is still true today, despite the widespread circulation of mischievous catchwords and clichés to the contrary.

INADEQUACY OF PERSONNEL AND RESOURCES

The correlation between family income and the adequacy of care received has a parallel in the correlation between community income and the availability of health and medical services.

At the beginning of the war, the United States as a whole was relatively well supplied with physicians. But the country-wide average of about 1 physician to each 750 people concealed wide variations from region to region, from state to state, and among urban and rural areas within states. The ratio was lower than average in low-income and in rural or sparsely populated areas. Specialists even more than general practitioners were concentrated in large cities and wealthy communities.

The lack of physicians in rural areas has been aggravated by the war; recruitment for the armed services was disproportionately heavy from states

and areas least able to spare them. It is probable that, with present methods of providing and paying for medical care, the return to peace and the demobilization of the armed forces will not bring improvement over the pre-war situation.

Maldistribution was even more marked among the dentists and probably among the nurses and hospitals. Where there was wealth, there were more or less ample personnel and facilities; where there was poverty, there was less or—in the extremest cases, even nothing.

Paying for medical care through individual purchase at the time the service is needed means inadequate care, insecurity, and burdensome costs for the patient. It also limits the financial security of the practitioners and institutions that furnish the service. The result appears in large variations in the incomes of practitioners, in low incomes for those who serve people of small or modest means, in inadequate financial support of hospitals, and—as noted before—in the maldistribution of professional personnel, hospitals, and other agencies.

The adequacy of public health services and facilities is also related to the prosperity or poverty of an area. Full-time, organized and adequate public health agencies are scarce enough the country over; they are especially deficient where wealth and income are less than average.

The unmet health needs of today include, in addition to those which I have mentioned, a few others of large importance. The need to strengthen the facilities for the education and training of personnel, to bring added support to research that will widen the boundaries of knowledge, to provide financial and technical aid for the construction of hospitals, health centers, and other facilities, I note only in passing; they will be examined at length by others

participating in this program. The need to improve quality of care, and to assure economy and efficiency in the provision of service, open the large and controversial questions which surround proposals for the organized group practice of medicine. This is not the occasion to examine the issues at length. But this much may be said: No solution to the financial problems of medical care has to wait until the group practice questions have been finally answered. And no solution would be a good one, if it either “froze” the *status quo* of individual practice or failed to aid and encourage widespread and constructive experimentation in the methods of providing care.

SCOPE OF A COMPREHENSIVE PROGRAM

This brief review of unmet health needs may be summarized in even more general terms. The first need is for more adequate services than we have yet developed to prevent the occurrence of illness—including community-wide preventive services, such as modern public health practice already furnishes more or less comprehensively in the more progressive and wealthier areas or communities; and individual preventive services, perhaps best exemplified in maternity-advice centers and well baby clinics. The second need is for measures to assure ready and equal access to medical services for illness in which the occurrence is not, or cannot be, prevented but in which the duration can be abbreviated, the suffering reduced, the severity moderated, and the aftereffects either prevented or minimized. Such measures must provide for development of the social institutions essential to stable financing and orderly administration of the services to be included within a comprehensive program of medical care. Each of these two broad classes of need can be met only through a variety of provisions, including means of dealing with deficiencies and mal-

distribution in personnel and facilities.

Let me emphasize the futility of discussions, like those which have been common in the recent past, as to which of the two programs is the more important, or which should precede and which should follow. Both are necessary; each is urgent; one complements the other.

WE CAN AFFORD THE COSTS OF HEALTH

It is fair to ask whether, as a nation, we can afford to meet the unmet needs that have been outlined. This, in effect, asks whether we can afford the price of that level of health and that freedom from suffering which modern science and skill have brought within our reach.

Before the war, total expenditures for medical services were about 4 billion dollars a year (exclusive of the cost of medical care for the armed forces). About three-fourths of this total was spent by patients and their families—the direct consumers of medical care. Four to 5 per cent was contributed by industry and philanthropy. The remaining 20 per cent was spent by federal, state, and local governments.

The 3 billion dollars spent by the American people in direct family expenditures for medical care represented about 4 per cent of consumer income. Families in the lowest income groups spent a larger average percentage. Expenditures of no more than these amounts, but under arrangements which assured the widespread availability of medical services, could vastly improve the adequacy of care and greatly advance the public health. If only these amounts were spent, but in such a way as to enable each family to pay an average amount—year in and year out—the burden on consumers would be far less than it has been. These amounts could adequately compensate those who provide the services under arrangements which would assure

them of regular incomes and, at the same time, avoid the unconscionable situation of having doctors without patients and sick people without doctors.

The pre-war level of expenditures for medical services, public and private, may not, however, have been fully adequate to pay the cost of services equal to our modern needs and standards. In the years ahead, especially if our economy operates with stability and at a high level of employment, our total expenditures for health and medical services might advantageously be expanded from the 4 billion dollars of pre-war years to as much as 5, 6, or even nearly 7 billion dollars a year under arrangements that will make adequate services and care available to the entire population. Those larger amounts for the future might be only 6 per cent of national income. This should be compared with the 5 per cent of national income (a total of about 3 billion dollars) expended about 10 years ago in times of deep economic depression when the degrees of economic freedom and the margins of flexibility in our expenditure patterns were very low indeed. These and all such figures should be measured against the 10 billion dollars commonly accepted as a conservative estimate of the direct and indirect annual costs of sickness and disability.

Like the growing and expanding social services generally, a strong health program is a necessity in every modern economy, because national wealth and well-being depend directly upon labor and productive work. There was a time when the social services were chiefly the gift of a few to the many, the charity of the rich to the poor. But today—and it will be more surely true in the future—the social services are for all, to be provided by the wealth and productivity of all. Moreover, the social services generally and the health services specifically are

not any longer to be financed by the "tax paying geese" that lay golden eggs; they are to be financed from the wealth of the entire society they serve. Modern society has been painfully and tragically slow in learning that the wealth of nations depends more upon the amount and the quality of the work we do than upon the amount of money we can avoid spending. As surely as health is prerequisite to work, so surely is it sound to earmark and spend for health up to the maximum that brings substantial returns.

Measured as a percentage of either family income or national income, we can afford health. In the words of a popular slogan, "it costs no more"; indeed, it costs less. We can less afford the higher price of sickness which we know how to prevent and of suffering, disability, and dependency we need not have. We are spending lavishly now for sickness and its consequences. We can resolve to spend wisely and productively

for health. Thus, within the limits fixed by available knowledge and skill, by our human and material resources, by our courage, energy, and vision, comprehensive and adequate health and medical services for all are within our means.

CONCLUSION

The economic barriers to adequate health and medical services are inherent in our present hit-and-miss methods of meeting the costs; they are not inherent in the nature of the services that are worth having, or in the nature or the capacity of our economy. If the services continue to be inadequate, the fault lies not in the stars but in ourselves.

The unmet needs can be met. How they will be met—and how rapidly—will be influenced by the rôle the public health profession will choose to play in planning and guiding a program of medical care for the nation.

Content and Administration of a Medical Care Program

A National Health Service: Scope, Financing and Administration *

NATHAN SINAI, DR.P.H., F.A.P.H.A.

Professor of Public Health, University of Michigan, Ann Arbor, Mich.

NO ONE, and least of all the public health worker, facing the facts of unmet health needs can escape the conclusion that a national health program is both desirable and inevitable. It is inevitable because the facts grow out of the daily experiences—the needs and the insecurity—of millions of people. These experiences are the exciting impulses behind the increasingly forceful demand for a more adequate distribution of the benefits of the health sciences. The chief issue, therefore, is not: Shall there be a national health program? Rather is it the much more technical question: How may the benefits of a national health program be distributed most successfully? This is the problem that should engage the attention and excite the imagination of the public health worker.

In its recommendations the Subcommittee on Medical Care has emphasized the elements of time and of orderly progress in the unfolding of a national health scheme. Desirable as it is to distribute the full benefits of science to the whole population immediately, the inadequacy of facilities and the unsatisfactory distribution of personnel make this an impossibility. Thus, the subcommittee visualizes an expanding pro-

gram covering a period of ten years, a period during which intensive efforts will be concentrated upon the problems of physical facilities and personnel.

The need at the outset is for a plan of comprehensive scope. Unless there is understanding and agreement concerning the whole scheme, there is grave danger that the parts that must ultimately comprise the whole will develop as unrelated and badly fitted pieces. The best hospital and health center construction program in the world, taken by itself, will result only in hundreds or thousands of magnificent monuments to the builders' art. Add to the construction program a plan to activate the physical facilities with adequate personnel, and each hospital or health center becomes a place where medical care *might* be available if the economic barriers between the services and the people were reduced or leveled. Introduce the third factor, that of prepayment, and the plan as a whole becomes a dynamic force in the distribution of adequate care. These, with one other, are the basic parts of a national health scheme; to think that any one of them—construction, or distribution of personnel, or prepayment—can attain the objective of satisfactory national health is to think in fictions.

In scope, then, the national health plan must be conceived as, ultimately, embracing all services — diagnostic,

* Presented before the American Public Health Association at the Seventy-third Annual Meeting in New York, N. Y., October 4, 1944.

curative, preventive. And, since the distribution of such services now varies so widely, the plan at its initiation must be flexible enough to permit the full utilization of the services that exist in different communities or areas of the country.

Possible methods of financing a national health service have been indicated by the chairman. Whatever the method or the combination of methods, it should be recognized that a large part of the total funds for medical care does not constitute "new money" in the sense that it will be expended for entirely new purposes. Much of the total sum would be expended if there were no national health plan, just as it is being expended today without providing for the benefits that are envisaged in such a plan.

An endless amount of time might be spent, and doubtless much time will be spent, in debate upon the relationships between the federal and state governments in a scheme of national health. Such debate is interesting and provocative, but this is not the subject that should be the main preoccupation of the great majority of public health workers. There is another subject, much more difficult and much more productive of values, that demands the chief concentration of public health.

Between the stated objectives of a national health plan and their actual achievement there exists a broad, deep gap. To the public health worker this is no new phenomenon; it has many parallels in his own fields of effort—maternal and child health, malaria control, food sanitation. If there is to be any satisfactory achievement the gap must be filled with the solid materials of successful administration. Successful administration, then, is the fourth basic elements in a satisfactory national health plan. Unfortunately, too little attention has been given to it.

Public health may make a valuable

contribution to all aspects of a national health plan; to its administration the contribution may be unique. Rare, indeed, is the health department that does not have within its own area some form or forms of medical administration. Whether it is the administration of the many types of federal, state, or local medical relief, or the present Emergency Maternal and Infancy Care program, or a Farm Security program, or a voluntary hospital or medical plan, much may be learned through critical examinations of the administrative processes. With many of these processes health departments are already involved and their accumulated experience has incalculable value—if it is accumulated.

Whatever may be the broad policy-making authority of the federal or the state governments, detailed administration must be centered where the people live and must be related to local conditions and needs. If administration is to become the function of any existing local agency, the health department is the logical choice. But, as always happens, the authority to administer is accompanied by specific and weighty responsibilities.

The first responsibility of the health department is to become acquainted with the existing administrative experience and technics. To say that "services must be rendered under conditions acceptable to the public and the professions concerned," has a soothing cadence. But for the administrator such relaxing phrases are not enough; he must prepare a written policy that sets forth precisely the acceptable conditions.

There is little doubt that one of the key problems of administration will involve the method or methods of payment for service, as well as the amounts that are paid. It is assumed also that, since it is the least departure from the traditional form of payment,

the fee-for-service will be the choice of the medical profession.

The local administrator owes it to himself, his department, and his community to become acquainted with the history and the administration of this form of payment. Furthermore, it is unfair to adopt or accept it with the assumption that it is foredoomed to failure. Under those circumstances failure is a certainty. The only fair approach is to apply to the method all of the administrative ingenuity that is possible and to devise new and more satisfactory technics of control. And on this subject the local health administrator will find, usually, that his own community has in it abundant research material.

The local administration of financing is not a necessary accompaniment of the local administration of services. Just as there are wide variations between the economic resources of states, so are there variations between districts or counties within states. Thus, while the local administration of services might be on a basis of the present or of reshaped health jurisdictions, the actual payment for services might be centralized for a number of such jurisdictions within one or more trade areas.

The point need not be labored that the administration of a national health plan calls for much more attention to those minute details that make up the daily administrative processes. It can be assumed that an over-emphasis upon paperwork will arouse antagonism. To the professions and the hospitals that anticipate and are prepared to resent this form of "red tape" it will come as a welcome evidence of administrative capability if paperwork is simplified. But simplification is never the result of just wishing for it. Too often are the

purposes of medical administrative records confused with those of medical research records. And, too often, the result is a cumbersome and complex combination that produces administrative irritations and, at the same time, inadequate medical research.

With the fee-for-service as the method of payment, administrative controls must be devised. Unless they are better than those of the past they will be resented both by the public and the professions as examples of "bureaucratic interference." It would be well for public health to adopt and then to seek the methods of applying the principle that a successful control procedure is one which is neither irritating nor burdensome to those who do not need to be controlled—and that means the great majority of the professions, the hospitals, and the public.

To think of a national health program starting tomorrow produces mixed reactions. The potential results excite enthusiasm, but the lack of sufficient administrative personnel and a body of evaluated administrative experience act as curbs. Not for a moment should anyone assume that these lacks will postpone the adoption and the initiation of a national plan. Public action is never postponed until all administrative details are completed, and it follows that the safest course for the administrator is to anticipate and prepare to meet the public demand. The only other course, that of doing nothing and waiting, leads to emergency administration. And the very thought of administering a national health plan as though it were an emergency is appalling. For public health this is a "get ready" period; its values will be high or low according to how intensively this period is used.

Content and Administration of a Medical Care Program

Problems of Administration of a Medical Care Program *

J. ROY HEGE, M.D.

*Health Officer, Forsythe-Stokes-Yadkin-Davie Health Department,
Winston-Salem, N. C.*

THIS paper deals with certain of the problems or issues in the administration of a health and medical care program and with the function of the health officer in relation to the program.

There is much discussion as to whether medical care administration should be on a wholly federal or on a federal-state-local basis. Whatever the force of arguments pro and con on this issue; it is plain that there must be decentralized control of health services, that the people of each local area must have a great deal of choice as to what their health services shall be and how they shall be administered. There must be latitude for different administrative arrangements and devices. Conditions and needs vary the country over and the state and its local communities should be free to develop arrangements best suited to their particular needs.

Our public health services have developed primarily on a state and local level of administration, and unless medical care is developed on the same basis, the possibilities of thorough-going integration will be greatly handicapped. Indeed, federal administration of curative services and state administration of preventive services would seem cer-

tain to perpetuate that separation of prevention and treatment which we wish to avoid, unless the state agencies assume major administrative responsibilities within the framework of a national program or system.

If it is assumed that the primary administrative responsibility for operation of the health care program will lie with the state, to what extent will the state government operate the program directly and to what degree will responsibility be delegated to local units of government?

It is obvious that this will vary in different states. The natural area for administration of a medical care program is the large metropolitan center with a variable amount of surrounding territory: the medical service area. Many communities are not self sufficient with respect to hospital and medical services. Rural people go into the nearby towns and small cities for physicians' services and, together with inhabitants of small towns and cities, go into the large metropolitan centers for certain types of specialist care and for care of major illnesses. In some states, especially those which have only one or two such medical service areas, it is almost inevitable that administration throughout the entire state will be by a state agency. Other states con-

* Presented before the American Public Health Association at the Seventy-third Annual Meeting in New York, N. Y., October 4, 1944.

tain more medical service areas, and here question will arise as to whether administration throughout should be by a single state agency or be delegated to local jurisdictions covering the several medical service areas. Special problems will be created by the numerous medical service areas which cross state lines.

It is quite likely that in some states it would be necessary, even with state administration, to divide the state into administrative districts, each such district comprising a medical service area. It might be necessary to develop, in some cases, a new, local governmental authority having responsibility for health services, because many existing county and city governments are unsatisfactory for this purpose. What is needed is a local authority which will have jurisdictional responsibility over an area roughly coterminous with a medical service area, i.e., combining city and countryside. Such a new local authority will have to be, in effect, a combination of several counties or of a city and several counties, in many states and parts of states.

The districts here envisaged for medical care administration would be appropriate for administration of public health services and of course should be identical. If such an integrated public health and medical care program is to be implemented, the district health authority should have a firm legal basis established by state legislation. Its board or council might well be made up of representatives of the councils or commissions of constituent counties or cities. Participation in this health district would have to be coercive upon the constituent counties—the district health authority could not function if constituent counties or cities could withdraw at will.

The next problem to be faced is the make-up of the state or district administrative unit. It is believed that responsibility for policy should be vested in a board composed of perhaps 10 to

20 members, part of whom should be representative of the medical profession, the hospitals, the dental profession, and other groups providing health services, but a majority of whom should be representative of the public. Such a board for state administration would be appointed by the governor, and for districts by the governing council (or other authoritative body) of the health district authority. Generally speaking, existing state boards of health would not be suitable for the responsibility without revision of their composition, since they usually have too many physicians in proportion to the representation of the general public. Responsibility for actual administration should be vested in a single person who would be responsible to the board. If the medical care program is largely or wholly financed by insurance contributions, there should be appropriate representation of the contributors as well as of those who furnish the services.

How will present health departments be integrated with the medical service administration? I am firmly of the opinion that ultimately all health services, both preventive and curative, at the state or at the district level, should be administered by one health agency. It is quite likely, however, that at the inception of the program some states will see fit to place administration of the medical service program in some agency other than the health department. Other states might vest administration in a reorganized department of health, in which what is now the health department would constitute a division responsible for preventive services.

Other factors to be given weight in considering the relationship of health departments to the new program are the potential size of the new programs and the inexperience of many present health department personnel in medical care administration. In terms of cost and number of personnel required for ad-

ministration, the new programs will dwarf the present public health programs. For these reasons, some states and localities may decide to set up a new agency to administer the new program. The degree of initiative shown by health departments in bringing about a medical care program and the extent of their eagerness to assume the responsibilities of its administration will undoubtedly be important factors in determining their relationship to the new program.

I think it may be assumed that any governmental medical care program, at least at the outset, will be merely a program for the payment of or distribution of medical services, and will be superimposed upon present methods of practice and provision of care with as little change in these methods as possible. In other words, general hospital care will continue to be provided mainly by voluntary hospitals as at present, and physicians' services will be provided by private practitioners paid on a fee or capitation basis—with some probably paid on whole- or part-time salaries or on salary payments combined with other kinds of payments. The main difference will be that hospitals and physicians will be paid out of an insurance or tax fund, contributed periodically on a group basis by sick and well alike, instead of being paid as at present, by the sick at the time service is rendered.

A technique of paying hospitals for their services from a central fund has been recently worked out by the Blue Cross Plans and the E.M.I.C. program; it has been done for a long time by public welfare agencies, medical care prepayment plans, etc. These methods can be used under a comprehensive health and medical care program. Techniques of paying for physicians' services from a central fund have similarly a long body of experience behind them and various alternative methods

are available for use. The same may be said of paying for dental and nursing services.

When arrangements have been developed for paying hospitals and physicians for their services out of a central fund, there will be opportunity for improving the quality of care. Indeed, these problems will become so pressing that they cannot be avoided. Once hospitals are being paid out of public funds for their services to the population, it will be important to set standards as to quality of care which institutions must meet in order to qualify as hospitals. It will also be necessary to develop standards of efficient administration to assure that costs are kept to reasonable levels.

The question of group practice is important. Group practice provides a means whereby the quality of service can be elevated and its cost lowered. I believe that group practice will develop within the framework of a medical care program and that the program can do much of itself to stimulate such development, but I do not believe that it will be possible or desirable to force group practice upon the profession under a medical care program. What can be done is to permit free competition between group and individual practice. That is, we should pay all physicians as nearly as practicable on the same basis for their services.

If some desire to form groups, and by so doing can provide better service and thereby attract more patients, or if they can reduce the expenses of practice and thereby increase their incomes, they and the public will reap advantages which will in time lead other doctors to form groups. In short, to the extent that group practice is beneficial to the profession, the profession will adopt it. Here and there we have already seen group practice stimulated or even organized by public

groups, either in group clinics or around hospitals.

Development of group practice can be aided and encouraged, at least in rural areas, by the construction of health centers. Such a center can provide offices for doctors as well as central laboratory and x-ray facilities. Bringing doctors into proximity with each other will facilitate development of co-operative effort. The health center also provides an opportunity for coördination of medical care with community-wide preventive services.

I am quite familiar with some of the problems of western North Carolina, and I am of the opinion that we should do something to meet these problems. I think we could tie up medical care and public health by expanding the services of our present health centers; first, by increasing the number so as to make a health center accessible to all the people and second, by providing adequate medical care services along with our preventive health program. All medical, hospital, and other essential diagnostic aids and services should be made available at or in coöperation with the health center facility. At present the communities are not in a position to provide modern medical aids for themselves. Rural practitioners are rarely financially able to purchase them, and sometimes do not fully appreciate the need for them.

Leaders in the medical profession for some time have been recognizing the inadequate distribution of physicians and the lack of available medical care throughout North Carolina, and especially the western rural sections. To meet these immediate needs it would be well to establish in the near future accessible health center facilities in some sections of our state, where present medical and hospital services are so inadequate. Each of the centers should be provided with trained medical, nursing, and other necessary profes-

sional personnel to serve adequately the medical care needs of the population in the area in which the center is located. The facility should provide all the essential health services, both preventive and curative. A rural or semi-rural health center facility should provide a minimum of one physician, one public health nurse, one clinic nurse, a combination historian and clerk, and a laboratory technician. In the larger population centers the health facility should accommodate a number of physicians, public health nurses, clinic nurses, etc. Each facility should be constructed, staffed, and equipped for the specific locality and type of services to be provided. In some isolated sections it might be advisable to provide a small number of hospital beds to take care of the emergency medical problems of the area. The health facility medical personnel would administer office hour medical services of all essential types, both preventive and curative, comparable to the services commonly rendered by general practitioners in their offices to ambulatory cases, and home visits to persons living throughout the area served by the particular health facility.

COMMENT

An endeavor has been made to touch upon some of the more important problems in the administration of a medical care program. It is evident that on many points we are not yet ready to give final answers. We shall have to learn by doing, and as we set ourselves to the task, the problems, I am confident, will become less complex. One can be sure that the answers found to these administrative problems the country over will not be uniform. In one state or locality we will do it one way, in another state, another way. Methods and arrangements must remain fluid, one giving way to another as experience prompts. The rôle of the

health officer in all this is not clear, and must depend upon the course of events and his own efforts, but his opportunity is large.

In paraphrasing the committee's report our chairman advised health officers to begin now preparing themselves for the position they should occupy in the new administration of a comprehensive medical care program. He also added a word of warning to the effect that if health officers failed to show the necessary competence and enthusiasm for the job, the public authorities might seek other leadership. This raises the question as to where and how a health officer might secure the necessary training and experience.

When more normal times return and the demands on employed health officers lessen, it will be advisable for them to pursue formal courses of instruction. Such courses should cover the elements of health insurance, public administration, and hospital management. Preferably a full academic year should be devoted to this work but, for those who cannot spare so much time, much of the same ground may be covered through short refresher courses. It is recognized that the curriculum in most schools of public health does not make provision for these subjects. However, once the demand develops, schools of public health may be relied upon to meet their responsibility for this area of interest.

More immediate steps in the way of preparation for enlarged responsibilities in the medical care field may be taken by the health officer himself on his own initiative. In many communities some provision within his health jurisdiction is made for care of the indigent sick. This function may be discharged by a physician for the poor; it may take the form of payments to practising physicians; or there may be a well organized clinic for the purpose. The health officer should interest himself in this service and accept responsibility for its administration. It will be enlightening for him to become acquainted with its problems. Within most health jurisdictions there will be general hospitals, and the health officer should interest himself in their management. If the hospital is operated by the local government, it might well be placed under the direction of the health department. If it is a voluntary hospital, the health officer might become acquainted with its policies by serving on its staff or on its board of directors. Thus it is evident that there are many ways in which a health officer might become identified, in a manner adapted to local circumstances, with current medical care activities. In doing so, he could be adding to his own information and at the same time infusing the public health concept into the operating policies of these institutions.

Content and Administration of a Medical Care Program

Hospitals and Hospital Construction *

GRAHAM L. DAVIS

Hospital Director, W. K. Kellogg Foundation, Battle Creek, Mich.

"THERE are extensive deficiencies in the physical facilities needed to provide reasonably adequate services. Such facilities include hospitals, health centers, and laboratories. The needs are most acute in poor communities, in rural areas, and in urban areas where the population has increased rapidly or where the development of facilities has been haphazard or the financial support inadequate." So reads the statement on needs as officially adopted by the American Public Health Association, and published in this issue.

To meet this need it is proposed by the Subcommittee on Medical Care that the American Public Health Association sponsor, in coöperation with the American Hospital Association and other health agencies, a post-war hospital and health center construction program.

FEDERAL PARTICIPATION

At the federal level the program, to be administered by the U. S. Public Health Service, would provide grants and loans for the construction of new buildings and the modernization, alteration, and enlargement of existing structures, including equipment, but not the purchase of land. In the general hospital category non-profit institutions, both governmental and non-governmental, would share in federal aid, but

it would be limited in the other categories (tuberculosis and mental hospitals, health centers, and other public health department facilities) to governmental institutions.

The federal government has established the precedent under the Lanham Act of financial assistance to non-governmental hospitals for emergency construction during the war. This principle is sound, because from the strictly legal standpoint the only difference between a governmental hospital and a hospital owned and operated by a non-profit corporation is in who holds title to the property. The board of trustees of the non-profit corporation in effect holds title and operates the hospital as a trust for the community it serves. For that reason it is exempt from taxation and enjoys other special privileges under the law. A study by the U. S. Public Health Service has shown that, for all practical purposes, the governmental general hospital serving all economic groups in the community is no different from the hospital owned and operated by the non-profit corporation. Its more or less autonomous governing board, usually appointed by the governing authorities, and its sources of income, ratio of free patients, and standards of service compare with its neighboring hospital owned and operated by a non-profit corporation.

Since governmental hospitals for the acutely ill and injured in the general

* Presented before the American Public Health Association at the Seventy-third Annual Meeting in New York, N. Y., October 4, 1944.

population care for only 10 per cent of all such patients and about 80 per cent are cared for in hospitals operated by non-profit corporations, limitation of federal assistance to governmental hospitals would not accomplish a great deal, unless the federal government builds hospitals to compete with existing non-governmental hospitals. That would not make sense, but in no event should federal funds be granted to a community for its hospital program where there is evidence of discrimination in the admission of patients on account of race, creed, or economic status.

STATE SURVEYS

Of equal and perhaps greater importance than federal aid with construction is the encouragement and assistance the Public Health Service will give each state with an inventory of its existing hospital and health department facilities and services and the planning of a long-range program intended to correct the weaknesses. This is a fundamental element in the program.

In most states the weaknesses are many and varied. As a general rule anybody anywhere can rent an old house, put some equipment in it, call it a hospital, and operate without supervision from any source. That is one reason why only 3,000 of the 10,000 institutions caring for the sick come up to the minimum standard for approval by the American College of Surgeons, and only 6,655 are registered by the American Medical Association.

Little is known on a national basis about the 3,000 or more other institutions of a nondescript character, because they are not subject to regulation except in two or three states and a few large cities. The absence of regulation and a definite plan and program for a national hospital service has caused duplication of effort in hospital construction and operation and the expenditure of tax funds and voluntary

gifts on several small and inefficient units in a given community when one large unit is clearly indicated to give the most efficient and economical service. It is not necessary to recount the weaknesses in the public health service to this audience.

Federal grants should be made immediately to the states for surveys, which would disclose what needs to be done to improve or replace existing facilities and where additional units should be constructed, but no construction would begin until a congressional decision or a presidential declaration that the war emergency has eased to the point that labor and materials are available. Until that time only limited and very urgent construction needs should be met.

The survey itself is preferably a function of the state and it may be organized in any one of several different ways. The state planning commission or the state health department might sponsor it, or the governor might appoint an independent commission. The state hospital association might follow the American Hospital Association pattern for the nation by the appointment of an independent commission financed by private philanthropy. The important thing is to get the facts, evaluate them, and develop a workable plan that will eventually provide the people with all the essential hospital care and public health service they need according to modern standards.

This Commission on Hospital Care¹ was appointed by the Committee on Post-war Planning of the American Hospital Association for the purpose of studying the nation's resources for the institutional care of the sick and to propose a plan of action intended to improve and more effectively utilize these resources. This approach to the problem presupposes the weaknesses that have been indicated in the present organization of hospital service. This

independent commission, broadly representative of hospital administration, medicine, public health, dentistry, nursing, the farmer, labor organizations, industry, and the general public, is financed for a two year period by grants of \$35,000 each from the Commonwealth Fund of New York, the National Foundation for Infantile Paralysis, and the W. K. Kellogg Foundation. Its report will be made to the nation and it plans to make detailed studies in Michigan and two or three other states from which a pattern will come for all of the other states to follow. This commission should work in close co-operation with the U. S. Public Health Service, and such coöperation is assured.

To carry out the state program will require legislation that will regulate the construction and operation of hospitals, including maintenance of high standards of service. Even the construction phase of the state program would be hampered without this co-operation on the part of the state, but where the state is slow or reluctant to act and the state health department, hospital association, local hospitals, and other health agencies will coöperate, the Public Health Service would be justified in making a study and assisting communities, hospitals, and health centers with construction in accordance with the master plan for the state. Federal aid should be available in such circumstances. Where the need exists, the probabilities are that the state government would eventually take action to make the program official, because of the pressure of public opinion.

When a state agency, such as the planning commission or the health department, sponsors the survey, the state (presumably through the governor) should appoint an advisory council composed of representatives from the hospitals, the health and architectural professions, labor, industry, agriculture,

the general public, and other state agencies responsible for providing hospital and medical care and public health services.

STATE DISTRIBUTION PLAN

The state program would include not only the facts gathered in the survey, but also a master plan which would show what facilities should be constructed and where and when. Due consideration should be given to the interrelation between existing and proposed facilities within each service district as blocked out by the state agency.

For hospitals the service district would in general follow the trade area of the larger centers of population and the strongest teaching and diagnostic centers, usually found in these larger places, would be the "primary" hospitals. The "secondary" hospital centers, generally less comprehensive than the "primary" centers with respect to staff, specialists, and physical facilities, would still be strong enough to serve the satellite "tertiary" centers within the area for consultative and specialist services, especially because the "secondary" centers should be effectively linked with the "primary" centers. The "tertiary" centers would include, but not be restricted to, the small hospitals and health centers in rural and semirural areas.

The master plan would also reflect due consideration for the provision of general hospital and health center facilities to serve the residents of rural areas and as a means of inducing physicians to locate in such areas. The desirability of combining hospital facilities with the housing of offices for physicians, dentists, clinics, and health departments should be stressed.

The community hospital and the local health department have grown up separately and have never become well acquainted with each other. Health service for the people is indivisible.

The most efficient service at the lowest possible cost requires complete coördination of its three major components—the physician, the hospital, and the health department. In rural America, where all three of these components are comparatively inadequate and application of the principles of coördination is much simpler than in the large cities, the community hospital might well become the community health or medical center by placing the health department and the offices of physicians and dentists under the same roof.

The logical person to direct this combined health program is the public health officer, but with rare exceptions hospital administration has not been his function in the past. The wise health officer will compensate for this lack of training by employing a competent assistant who is experienced in hospital administration or by using as a consultant an experienced administrator in the nearest large city. Hospital administration may eventually become a part of the curriculum in the school of public health.

STATE ADMINISTRATION

A single state agency would be responsible for administration of the program (covering all types of eligible facilities) which would develop following approval of the state distribution plan. This would preferably be the same state agency which made the survey of resources and needs and formulated the state distribution plan. It is anticipated that it would be a different agency only in those states in which the creation of a new agency would be necessary for participation in this program and, in order to avoid delays, a temporary agency was created to initiate state action and to be responsible for the groundwork on the program until a more permanent state agency could be created. The responsibilities of this state agency administer-

ing the program would include the preparation of the state's periodic requests for federal funds, determination of the eligibility of individual projects to share in the federal funds, coördination of existing facilities so as to carry out the state agency's districting system, and supervision of the scheduling and progress of construction to insure adherence to the state plan.

In determining the eligibility of individual projects for participation in federal funds, assurance of the individual soundness of the project and of its conformity with the state plan from such standpoints as need for the facility, type of service, location, size, and co-ordination with other facilities within the same district would be necessary. There would have to be reasonable assurance of an adequate staff organization, efficient management, and proper financial support for effective operation when construction was completed. Plans and specifications would be approved by the Public Health Service prior to construction contract award, for no project would be eligible for federal aid without that prior approval.

The grants-in-aid to the states would be on a variable matching basis and the availability of funds to cover the non-federal contribution to the project would have to be assured. These funds might come from several different sources. The state, county, or municipal governing authorities might make contributions from tax funds, or from funds raised by bond issue, or by loans from the federal government. Private philanthropy would come strongly into the picture, as it always has in the past. The raising of the local contribution by mortgage on the non-governmental hospital should be discouraged and perhaps prohibited entirely.

FEDERAL ADMINISTRATION

The Surgeon General would, with the approval of the Federal Security Ad-

ministrator, issue regulations for the administration of this program. He would be advised by a council appointed by the Federal Security Administrator, or by the Surgeon General with the approval of the Administrator, and representing hospitals, the medical profession, public health agencies, the architectural profession, labor, industry, agriculture, and the general public.

The Public Health Service would, in coöperation with the professional organizations concerned, develop, for the guidance of the states, standards for the various categories of eligible facilities, pointing up necessary elements of construction and their interrelation.

SUMMARY

The major objective of this program would be a planned distribution of hos-

pital and health center facilities that would serve all residents of those states and jurisdictions electing to participate. The planning would be done by the states, since planning at that level affords greater perspective than planning at a more local level, and at the same time assures consideration of area differentiations. The federal rôle would be pointed toward minimum supervision and maximum assistance in planning both the individual project and the general distribution of hospital and health center services for the purpose of providing each community with the best possible facility from the standpoints of architectural planning and economy of operation.

Content and Administration of a Medical Care Program

Training of Personnel and Research *

GEORGE ST. J. PERROTT, F.A.P.H.A.

*Chief, Division of Public Health Methods, U. S. Public Health Service,
Washington, D. C.*

THE provision of a comprehensive program of medical care requires a comprehensive plan for the training of personnel and their distribution on the basis of the needs of the population. The maintenance of a high quality of medical service, improvement of therapeutic technics, and the introduction of economies resulting from discoveries of methods of disease prevention are the objectives of the research which is a second essential foundation for a comprehensive medical care program. These basic principles have been recognized by the Subcommittee on Medical Care and are embodied in Recommendations VI, VII, and VIII of its Preliminary Report.

A nation-wide program of health and medical services will require the co-ordinated action of a wide variety of professional and technical personnel, including general practitioners, specialists, dentists, nurses trained for general bedside care, public health and other nursing specialties, medical social workers, sanitary engineers, health educators, laboratory specialists and the technicians, and auxiliary personnel required in hospitals, clinics, and health departments. An adequate health program will require greatly increased numbers of personnel in all of these fields. Numerous educational institutions, health and medical agencies and

organizations must coöperate in a training program of this scope.

Physicians, nurses, and lay administrators must be trained for the specific administrative and supervisory duties of the medical care program. Expansion of the preventive services provided by health departments will require additional physicians trained as health officers and administrators of special activities, and public health nursing supervisors. As an immediate adaptation of such training to the personnel needs of the future, the subcommittee recommends that state health departments should utilize funds now available to prepare these personnel for the administration of medical as well as health services. This recommendation of the subcommittee is of special significance to this Association, since the necessary action on the part of state health departments and the schools of public health, more than any other single activity, may determine the rôle of the official health agency in the health program of the future.

The major emphasis of the research supported as part of a comprehensive health program should be placed on the control of diseases the care of which by present methods is so costly as to be difficult to finance adequately even with tax support. Mental disease, dental caries, rheumatic fever, particularly in its relation to the broad problem of diseases of the heart, and the processes of aging are among the fields

* Presented before the American Public Health Association at the Seventy-third Annual Meeting in New York, N. Y., October 4, 1944.

of research which should be subsidized from public funds. In addition, provision should be made for personnel research, administrative studies, and experimental demonstrations required for the improvement of organized methods of distributing health services, and the support of basic research by the faculty of educational institutions which is essential to the maintenance of professional standards.

TRAINING OF PERSONNEL

Scope of the training program—The training program is concerned with the basic and postgraduate education provided by medical schools, schools of public health, dental and nursing schools, by selected departments of university graduate schools, and with certain types of technical and vocational training below the professional and graduate levels. However, its educational objectives extend beyond pre-induction training to training in service; hospitals, clinics, state and local health departments, special educational demonstrations, field training centers, and professional public health and medical associations must be coordinated in the general program.

The training program should include funds for the following purposes:

1. Scholarships for unusually gifted students who otherwise might not be able to pursue basic health and medical education
2. Grants for postgraduate education of health and medical personnel, including refresher courses
3. Grants for the promotion of postgraduate education among the faculty of the professional schools concerned
4. Grants to aid in the organization of new training and demonstration facilities required, including professional schools, individual university departments, coordinated facilities for continuation study, field training centers and experimental demonstrations
5. Support of studies to aid in the wise allocation of training funds, including periodic estimates of overall personnel needs, methods of selecting properly qualified trainees, re-examination of the content of various basic

professional curricula, and the development of criteria for the approval of educational and other institutions participating in the program

Medical education—It has been estimated that as many as 25,000 additional physicians might be required to render adequate service to the post-war population. Continuation after the war of the present emergency program in medical schools until the physician deficit is removed would be one way of meeting the issue. However, under the most favorable circumstances, not for some time to come is it likely that such an increase in physician output can be anticipated. As an immediate adjustment to the situation, it is extremely important that the time and energy of physicians be utilized to full capacity.

To this end, the training program should make special provision for the appraisal and possible extension of existing facilities for the training of established types of medical technicians and other auxiliaries, and for investigations of methods of utilizing new types of subordinate personnel. Large well organized clinics have recognized the economy in having such services as admissions, history taking, temperature and blood pressure readings performed by non-medical personnel. While the utilization of such auxiliaries would increase the time available for professional service by the private practitioner, his individual resources cannot support their employment at present. The increase in group practice which would probably take place under a comprehensive plan of medical care should increase the utilization of nurses, laboratory and x-ray technicians, and other technical personnel in the performance of many services which the individual practitioner now provides singlehanded. The technic of the job analysis should be applied to the physician's working schedule, under conditions of both individual and group

practice, to determine the possibility of transferring additional technical procedures to appropriate subordinate personnel.

In addition to an increase in the number of physicians, a major need in the field of undergraduate medical education is a reorientation of the present curriculum. There should be increased emphasis in undergraduate medical teaching on methods of keeping well people well. Furthermore, the content of the course in preventive medicine should be widened to include the broad field of organized medical care, comprising both prevention and treatment, and a consideration of the social factors involved. Such revisions of the medical curriculum eventually should produce medical practitioners whose basic training has prepared them to meet the objectives of a comprehensive health service. It is hoped that a by-product of such changes in undergraduate medical education would be the presentation of administrative medicine and public health as desirable fields for specialization.

Within the resources of the program, financial aid should be made available to hospitals to raise the educational standards of the internship and residency according to the principles formulated by the Commission on Graduate Medical Education.¹ Funds should be provided to enable hospitals to support residencies in critical specialties which would not otherwise be offered, and to encourage their election by an adequate number of qualified candidates.

Medical schools and hospitals should be coordinated in a broad program of continuing education for general practitioners and specialists after they have entered practice. At the outset, a formal system of continuation study should be organized. As the construction of hospitals, clinics, and health centers provided under the national program proceeds, increasing facilities for clin-

ical experience and consultation, the education of the general practitioner will become in fact continuous, and formal courses less necessary. The program of postgraduate education for general practitioners should include organized periodic refresher courses in clinical medicine and opportunities for short periods of intensive study of individual subjects. The Committee on Post-war Medical Service and the Council on Medical Education and Hospitals of the American Medical Association are now actively engaged in planning to meet the training requirements of physicians in the period of demobilization. The coöperation of the Public Health Service, Veterans' Administration, of hospitals, medical schools, American boards in the medical specialties, and other agencies in these plans for post-war medical training suggest the type of joint effort which will be required in a national training program.

Graduate education in public health—

Medical administrators required to coordinate services at the local level will present an urgent personnel need under a comprehensive medical care program. The subcommittee believes that the schools of public health are the appropriate training institutions for personnel of this type. The curriculum of the leading schools of public health has been developed to meet the needs of two broad classes of trainee, medical and non-medical. The basic curriculum now offered for medical trainees, typified by the health officer, should be revised to meet the training needs of other types of medical administrators, including those required in local medical care programs, and in the administration of hospitals, clinics, and health centers. In the construction of this basic curriculum in administrative medicine and public health, attention should be given to the need for instruction in the principles of administration, including per-

sonnel management, staff education, program planning, and the financial procedures involved in the administration of public agencies. Additional courses should be introduced to permit medical trainees to elect specialization in the administration of medical care programs, the administration of hospitals or other medical agencies, general public health administration, or the administration of special public health activities such as venereal disease control, tuberculosis control, etc. While no single school should be expected to develop so broad an educational program, facilities for training in all of these specialties should be available in one or another of the schools of public health.

Finally, it is desirable that the training program in organized medicine and public health include field experience in agencies providing the types of service which the trainees plan to enter. The high cost of maintaining field training centers with adequate full-time teaching staff will limit greatly the number of these centers which the schools of public health can provide. Financial support of such centers in health departments and other agencies in a number adequate to meet the needs of the national training program should be provided as part of the overall costs of medical care.

Approval of existing schools of public health for financial aid under a national medical care program should be based on their satisfaction of appropriate educational standards. The Association of Schools of Public Health in coöperation with the Public Health Service is now engaged in a preliminary appraisal which will contribute some bases for rating the effectiveness of the schools. However, extension of personnel research is a prerequisite for the construction of an adequate curriculum for the schools of public health.

The post-war population would require 4,100 physicians to staff its local

health departments if each population unit of 100,000 had a health officer and two medical bureau directors; in addition, it is estimated that 1,400 physicians would be required by the state health departments and the U. S. Public Health Service. This combined total of some 5,500 public health physicians required under an expanded public health program exceeds by 2,400 the number of public health physicians employed before the war. Such a shortage of public health physicians, combined with the need for administrators of the medical care program, might greatly increase the number of medical trainees seeking admission to the schools of public health in the post-war period.

It is estimated that immediately prior to the war the schools of public health had a combined capacity for approximately 200 medical trainees as candidates for graduate degrees or certificates requiring at least one full academic year of study. The facilities of some of the existing schools of public health probably could be expanded to accommodate a small number of additional medical trainees, but new schools would be essential if the increase in applicants were substantial. Financial aid to promote the expansion of existing schools of public health and the organization of new schools should be included as part of the essential costs of the program. With respect to non-medical public health personnel, studies should be undertaken to determine the appropriate training field of the schools of public health and of other educational institutions. For example, it seems possible that expansion to provide additional training facilities for certain types of technical (non-medical) public health personnel could be made with greater economy by the graduate schools of certain universities than by the schools of public health. Investigation of facilities for the training of technical public health personnel not requiring education at

the graduate level should form part of this program of studies.

The effective use of training opportunities provided under the program should be insured by the selection of trainees having personal qualifications for the type of position they expect to fill. An essential requirement of a system of trainee-selection for administrative medical personnel is a field center in which the trainee's aptitude for administrative duties may be appraised before he enters a period of formal training at a school of public health. New York State has devised a system which includes a field assignment of 6 to 12 months' duration, rotating among the state health districts with final observation in the central office.² However, the needs of the training program may require federal assistance in the selection of trainees. Such assistance might take the form of a national screening center for potential trainees, or a decentralized system developed in the field training centers.

Training of nursing personnel—While available estimates of the number of nurses needed for a comprehensive health and medical care program are not in agreement, they rest on the common assumption that the volume of nursing service will be increased greatly. A considerable body of professional opinion believes that this need should be met by a gradual reduction in the number of graduate professional nurses trained each year with an improvement in their educational program, accompanied by a gradual increase in the number of vocational (practical) nurses. It has been estimated that in its tenth year of operation a program of adequate public health and medical services would require about 300,000 graduate professional nurses, annual admissions of about 30,000 students to professional schools of nursing, and about 180,000 vocational nurses. This compares with present figures of about

260,000 graduate nurses (including those in the armed forces), 65,000 admissions to professional nursing schools, and about 70,000 auxiliary personnel.

Under an expanded health program, it seems probable that public funds would be needed to train the required number of graduate nurses for public health, psychiatric practice, and other specialties, as well as to support an adequate training program for vocational nurses. The use of auxiliary personnel in the field of nursing should receive special study in view of the probable shortage of professional nurses. Under the supervision of graduate nurses, auxiliary nursing personnel can give effective service in public health clinics, in the school health program and in selected types of home visiting. The war has demonstrated the value of nursing auxiliaries in institutional care of the sick. Aside from the need for funds, the training program should provide for technical studies bearing on the development of educational standards for the training of vocational nurses and other nursing auxiliaries. In this connection, it is of interest that the U. S. Office of Education at present is sponsoring a plan for the organization of an educational institution to train vocational nurses, supported by Smith-Hughes funds.

Personnel problems in dentistry—The present disparity between the receipt of dental care and the true dental needs of the population is so marked that society probably could not support its correction solely through an increase in the number of dentists. In the immediate pre-war period (1940), approximately 70,000 dentists were engaged in practice. Klein has estimated that approximately 130,000 dentists, or almost twice the pre-war number, would be required for the care of the dental disease and defects incident each year; and with the present capacity of dental schools doubled, their training would

take more than a generation. This estimate does not take into account the dentists required to care for accumulated dental needs.³

Long-range planning is therefore essential for the ultimate provision of adequate dental care. A fundamental requirement of such a program is the initiation of research in the cause and control of dental disease. A second essential is the eventual elimination of the problem of accumulated dental needs by the provision of the dental services required each year to maintain the dental health of children. Continuing research in methods of increasing the productivity of the available dentists offers a third approach to the problem. Klein has shown that the simple expedient of adding an extra chair to an individual dentist's office increases the volume of work he performs by 25 per cent, and the addition of a chair and a dental assistant, by 63 per cent.⁴ Exploration of new uses for dental assistants, dental hygienists and other auxiliary personnel offers a means of further increasing the productivity of dentists. While dentists probably could assign many of their operations to dental hygienists, only 3 per cent of the dentists included in Klein's survey employed dental hygienists.⁴ Thus, in dentistry as in medicine and nursing, studies of the more effective use of auxiliary personnel, and financial assistance for their training and utilization are an essential part of the broad personnel program.

Distribution of service personnel—The subcommittee has recommended that professional and financial stimuli should be devised to encourage physicians, dentists, nurses, and others to practice in rural areas. Plans to encourage the rational distribution of physicians should be developed as quickly as possible in view of the coming demobilization of the armed forces. Since diagnostic and therapeutic tech-

nics are constantly changing, alert and ambitious physicians have been reluctant to locate in rural areas where professional association is restricted and hospital and laboratory facilities are inaccessible. As hospitals and related facilities are provided in the rural areas, rural practice will become more attractive to young physicians, and their continuing education will be assured.

The immediate need, however, is an integration of the services of hospitals and health centers to make available to physicians in smaller cities and rural areas the educational advantages of these institutions. Periodic refresher courses should be provided in the large medical teaching centers. Establishment and support of a corps of substitutes to carry on the work of physicians during absence from their communities while attending refresher courses, should serve as a stimulus to broad physician participation in such a program. The circuit courses developed by some of the state medical societies represent a type of course adapted to physicians in areas remote from the large teaching centers. The postgraduate medical program conducted by the Bingham Associates Fund in coöperation with the Tufts College Medical School is an interesting example of a decentralized training plan for physicians in the small communities of New England.⁵

Finally, steps must be taken to equalize the income of urban and rural practitioners. Arrangement — either through insurance or tax supported plans—to compensate for the inability of many individuals to purchase medical care may accomplish this end only in part. As a further incentive to physicians to settle in rural localities, it may be necessary to provide government financial aid for rural practitioners. By this means it may be possible after the war to attract physicians to the communities most in need of

medical service. Particularly, demobilized physicians, who entered military service after the completion of intern training and left no established practice, might be amenable to this arrangement.

To assure a continued supply of young physicians to rural areas, consideration might well be given to the feasibility of financial aid for the basic education of medical students who agree to serve in rural areas. Under such a system, assignment of new graduates to under-staffed communities should be facilitated.

RESEARCH

The subcommittee has recommended that funds for the support of research be included in the overall costs of a comprehensive medical care program. Funds should be made available to federal, state, and local governmental agencies for research and for grants-in-aid to private non-profit institutions for the support of basic laboratory and clinical research and for administrative studies and demonstrations designed to improve the quality and lessen the cost of services. It is the belief of the subcommittee that governmental action is necessary in health and medical research to insure the continuity of research programs and to facilitate the coöperation in the research problems in this field of the variety of professional skills so often necessary for their solution. Some of the work should be done in federal government centers and a large part in state and local educational and other institutions, public and private, assisted where necessary through grants-in-aid. In other words, there should be planned action and the coöordinated activity of research workers in medicine and its underlying sciences, engineering, statistics, economics, public administration, and the other great variety of fields having a part to play in the development of a program of health and medical services.

The research problems selected for public support would be those whose solution would bring a substantial improvement in health and a reduction in the costs of the national medical care program. The national research program should give early attention to administrative studies of methods of distributing medical services appropriate to the varying needs of urban and rural groups. The pattern of a program for organized home and office care of the sick is being established by the prepayment plans now operating under state and local medical societies, industry, and various consumer groups, and by the existing system of public medical care. However, governmental support of experimental demonstrations and other research projects in this field will be essential to supply the technical information required to direct expansion of the medical care program. Personnel research is a related field of investigation which should be supported from public funds, and experimental demonstrations and field centers will be required where the effectiveness of new types of subordinate personnel as professional aides may receive practical testing.

The program should support research studies of problems emerging from new and special situations which are beyond the resources of private research institutions alone. Examples of such fields of investigation are the tropical diseases, medical climatology, and the potential industrial health hazards resulting from the use of new materials and processes developed during the war. Aside from the special health problems of industry created by the war, the program should provide for an adequate expansion of the industrial hygiene research in progress prior to the war. Research in this field is of recent origin in this country. Because of the variety of professional skills and the specialized laboratory facilities required in the investi-

gation of industrial health problems, public support is essential to the extension of our knowledge of methods of protecting and improving the worker's health. Research in industrial feeding is an allied project for which public funds should be made available. In addition, nutrition research should provide support of investigations in the prevention and diagnosis of the deficiency diseases, and methods of nutrition education.

A coördinated program of research on dental caries and other oral diseases is another major field of investigation requiring public support. It has been shown that a community water supply containing small concentrations of fluorides materially decreases the incidence of dental caries. A broad program of studies of the epidemiology of this disease and the possibilities of fluoride therapy holds promise of discovering a basis for its control. Research in other oral diseases is equally urgent. In no other field of public health is the demand for research more pressing or the etiology more obscure.

The nervous and mental diseases should receive major emphasis in a national research program. While a large proportion of public funds for medical care is diverted to institutional care of the mentally ill, there is relatively little public support of research

in methods of prevention of mental disease. The cardiovascular-renal group of diseases provides another example of the chronic diseases presenting urgent research problems which are being approached inadequately through private effort. Public support of research in tuberculosis, cancer, and the venereal diseases already has received legislative and professional approval. A national research program should extend public funds for research in the chronic diseases and in the general problems associated with aging.

The central coördination of research activities in these major fields will be essential to the effective operation of the program and the evaluation of results. It is believed that research facilities under the direction of an appropriate federal agency should be organized to fulfil this function. These centers would include laboratories and clinical facilities for research as well as the necessary administrative activities.

Medical Care in a National Health Program

An Official Statement of the American Public Health Association
Adopted October 4, 1944

AT the annual meeting of the Committee on Administrative Practice of the American Public Health Association, October 9, 1943, the committee directed its Subcommittee on Medical Care to draft a set of principles expressing the desirable content of a comprehensive program of medical care, the methods of its administration, and the part which public health agencies should take in its operation. In pursuit of this assignment, the subcommittee completed a tentative draft, which was considered and adopted by the Committee on Administrative Practice at its meeting, October 1, 1944. The report was then transmitted to the Governing Council of the Association where, after certain revisions, it was adopted as a statement of Association policy.

Because of its composition and charge, the subcommittee has limited its considerations to one sector of a comprehensive national health program, namely, medical care.

In preparing the report, the subcommittee has considered:

A. The needs for a national program for medical care

B. The objectives of such a program

C. Recommendations for immediate action

The American Public Health Association through its national organization and its constituent societies stands ready to collaborate with the various professional bodies and civic organiza-

tions which may be concerned with either the provision or receipt of medical service with a view to implementing the following general principles:

A. THE NEEDS

I. A large portion of the population receives insufficient and inadequate medical care, chiefly because persons are unable to pay the costs of services on an individual payment basis when they are needed, or because the services are not available.

II. There are extensive deficiencies in the physical facilities needed to provide reasonably adequate services. Such facilities include hospitals, health centers and laboratories. The needs are most acute in poor communities, in rural areas, and in urban areas where the population has increased rapidly or where the development of facilities has been haphazard or the financial support inadequate.

III. There are extensive deficiencies in the number and the distribution of personnel needed to provide the services. Here again, the needs vary according to categories of personnel and to characteristics of communities.

IV. There are extensive deficiencies in the number and categories of personnel qualified to administer facilities and services.

V. Many communities still are not served by public health departments; others inadequately maintain such departments. Thus, some communities

have never utilized organized health work to reduce the burden of illness, and others share its benefits only in part. In these communities especially, people lack information on the benefits of modern medical care.

VI. Expansion of scientific research is urgently needed. Despite past and current scientific advances, knowledge as to the prevention, control, or cure of many diseases is lacking.

Each of the six conditions defined above can be broken down into many component parts representing specific needs. In general, however, solutions of these broad problems require simultaneous attack on four fronts: namely, the distribution of costs, construction of facilities, training of personnel, and expansion of knowledge.

B. THE OBJECTIVES

I. A national program for medical care should make available to the entire population all essential preventive, diagnostic, and curative services.

II. Such a program should insure that the services provided be of the highest standard, and that they be rendered under conditions satisfactory both to the public and to the professions.

III. Such a program should include the constant evaluation of practices and the extension of scientific knowledge.

C. RECOMMENDATIONS

The recommendations presented in this report represent guides to the formulation of a policy for action. It is believed that study of these recommendations by the professions and others concerned in the states and localities will produce new and more specific recommendations for the attainment of the objectives of a national health program.

Recommendation I. The Services

a. A national plan should aim to pro-

vide comprehensive services for all the people in all areas of the country. In light of present-day knowledge, the services should include hospital care, the services of physicians (general practitioners and specialists), supplementary laboratory and diagnostic services, nursing care, essential dental services, and prescribed medicines and appliances. These details of content must remain subject to alteration according to changes in knowledge, practices, and organization of services.

Because of inadequacies in personnel and facilities, this goal cannot be attained at once; but it should be attained within ten years. At the outset, as many of the services as possible should be provided for the nation as a whole, having regard for resources in personnel and facilities in local areas. The scope of service should then be extended as rapidly as possible, accelerated by provisions to insure the training of needed personnel, and the development of facilities and organization.

b. It is imperative that the plan include and emphasize the provision of preventive services for the whole population. Such services include maternity and child hygiene, school health services, control of communicable diseases, special provisions for tuberculosis, venereal diseases, and other preventable diseases, laboratory diagnosis, nutrition, health education, vital records, and other accepted functions of public health agencies, which are now provided for a part of the population.

c. In so far as may be consistent with the requirements of a national plan, states and communities should have wide latitude in adapting their services and methods of administration to local needs and conditions.

Recommendation II. Financing the Services

a. Services should be adequately and securely financed through social insur-

ance supplemented by general taxation, or by general taxation alone. Financing through social insurance alone would result in the exclusion of certain economic groups and might possibly exclude certain occupational segments of the population.

b. The services should be financed on a nation-wide basis, in accordance with ability to pay, with federal and state participation, and under conditions which will permit the federal government to equalize the burdens of cost among the states.

Recommendation III. Organization and Administration of Services

a. A single responsible agency is a fundamental requisite to effective administration at all levels—federal, state, and local. The public health agencies—federal, state and local—should carry major responsibilities in administering the health services of the future. Because of administrative experience, and accustomed responsibility for a public trust, they are uniquely fitted among public agencies to assume larger responsibilities and to discharge their duties to the public with integrity and skill. The existing public health agencies, as now constituted, may not be ready and may not be suitably constituted and organized, in all cases, to assume all of the administrative tasks implicit in an expanded national health service. Public health officials, however, should be planning to discharge these larger responsibilities, and should be training themselves and their staffs. This preparation should be undertaken now because, when the public comes to consider where administrative responsibilities shall be lodged, it will be influenced in large measure by the readiness for such duties displayed by public health officers and by the initiative they have taken in fitting themselves for the task.

b. The agency authorized to ad-

minister such a program should have the advice and counsel of a body representing the professions, other sources of services, and the recipients of services.

c. Private practitioners in each local administrative area should be paid according to the method they prefer, *i.e.*, fee-for-service, capitation, salary, or any combination of these. None of the methods is perfect; but attention is called to the fact that fee-for-service alone is not well adapted to a system of wide coverage.

d. The principle of free choice should be preserved to the population and the professions.

e. State departments of health and other health agencies are urged to initiate studies to determine the logical and practical administrative areas for a national medical care plan.

Recommendation IV. Physical Facilities

a. Preceding, or accompanying, the development of a plan to finance and administer services, a program should be developed for the construction of needed hospitals, health centers, and related facilities, including modernization and expansion of existing structures. This program should be based on federal aid to the states and allow for participation by voluntary as well as public agencies, with suitable controls to insure the economical and community-wide use of public funds. The desirability of combining hospital facilities with the housing of physicians' offices, clinics, and health departments should be stressed.

b. Federal aid to the states should be given on a variable matching basis in accordance with the economic status of each state.

c. Because of its record of experience and accomplishment in this field, the U. S. Public Health Service should administer the construction program at

the federal level, in coöperation with the federal agencies responsible for health services and construction.

d. Funds available under this program should be granted only if:

(1) The state administrative agency has surveyed the needs of the state for hospitals, health centers, and related facilities, and has drawn up a master plan for the development of the needed facilities (taking account of facilities in adjacent states); or, in the absence of a state plan, the project is consistent with surveys of construction needs made by the U. S. Public Health Service;

(2) The proposed individual project is consistent with the master plan for the state; its architectural and engineering plans and specifications have been approved by the state agency and/or the U. S. Public Health Service; and there is reasonable assurance of support and maintenance of the project in accordance with adequate standards.

e. State health departments are urged to conduct studies to develop state plans for the construction of needed hospitals, health centers, and related facilities. Such studies should be made in coöperation with official health agencies, with state hospital associations, and other groups having special knowledge or interests.

Recommendation V. Coördination and Organization of Official Health Agencies

a. The activities of the multiple national, state, and local health agencies should be coördinated with the services provided by a national program. There is no functional or administrative justification for dividing human beings or illnesses into many categories to be dealt with by numerous independent administrations. It is difficult to reorganize agencies or to combine activities, and this cannot be

accomplished hurriedly. Therefore studies and conferences should be undertaken without delay at the federal level, and in those states and communities where the health structure is already unnecessarily complex.

b. The federal and state governments should provide increased grants for the extension of adequate public health organization to all areas in all states. Increased federal grants should be made conditional upon the requirement that public health services of at least a specified minimum content shall be available in all areas of the state.

Recommendation VI. Training and Distribution of Service Personnel

a. Within the resources of the program, financial provisions should be made to assist qualified professional and technical personnel in obtaining postgraduate education and training.

b. The plan should provide for the study of more effective use of auxilliary personnel (such as dental hygienists, nursing aides, and technicians), and should furnish financial assistance for their training and utilization.

c. Professional and financial stimuli should be devised to encourage physicians, dentists, nurses, and others to practise in rural areas. Plans to encourage the rational distribution of personnel, especially physicians, should be developed as quickly as possible, in view of the coming demobilization of the armed forces. Such plans should be integrated with the whole scheme of services and the establishment of more adequate physical facilities.

Recommendation VII. Education and Training of Administrative Personnel

a. Education and training of administrative personnel should be encouraged financially and technically, especially for those who may serve

as administrators of the medical care program, for hospital and health center administrators, and for nursing supervisors.

b. State health departments should utilize those funds that may be available to train personnel in such technics as administration of health and medical services, and hospitals. Such a training program may contribute more than any other single activity to the future rôle of the official public health agency. As a corollary, the attention of schools of public health is directed to the importance of establishing the necessary training courses.

Recommendation VIII. Expansion of Research

a. Increased funds should be made available to the U. S. Public Health Service and to other agencies of government (federal, state, and local), and for grants-in-aid to non-profit institutions for basic laboratory and clinical research and for administrative studies and demonstrations designed to improve the quality and lessen the cost of services.

b. The research agencies and those responsible for making grants-in-aid should be assisted by competent professional advisory bodies to insure the wise and efficient use of public funds.

Educational Implications of the School Health Program*

GEORGE M. WHEATLEY, M.D., M.P.H., F.A.P.H.A.

*Assistant Medical Director, Metropolitan Life Insurance Company,
New York, N. Y.*

THIS war is an opportunity and a challenge to health education. Youth and adults easily grasp the importance of total fitness in war. This is illustrated by the results of medical examinations of high school boys for the Physical Fitness Victory Corps Program. A substantial number of these youths are found to have physical abnormalities which are amenable to treatment. It has been a common experience in many parts of the country that within a few months practically 100 per cent of the boys have secured medical attention. A study of their previous medical records has shown that the vast majority have had their physical defects for some years—without securing treatment. Herein lies one of the unknown elements of health education. We apparently have yet to learn how to get action. Yet, incentives for physical fitness are not necessarily dependent upon a war atmosphere for a desire for war service. In peacetime the same quick response is observed in connection with the medical examination of girls and boys who apply for working papers. The urgency of a prospective job leads to their securing treatment for conditions which have existed and been known to them for some time. But the point is that, in war or peace, too fre-

quently some other factor, not the health examination, is the motivating force which produces action.

The other day a school administrator, in discussing this problem, said: "You know, that reminds me of something I haven't thought of for years. When I was in grammar school, my sister brought home a cryptic note from school saying she needed glasses. My father simply ignored it. A few days later I brought home a note which stated the same thing. My father only laughed and said, 'The school people don't know what they are talking about; you don't need any glasses.' A few weeks later we went to a baseball game together. The game was under way when we arrived, and as we settled ourselves in our seats, my father asked the score. When I looked over to the scoreboard all I could see was a blur. So I told him I didn't know what the score was. He said 'Look at the scoreboard and see.' I had to confess I couldn't see the numbers. The next day my sister and I got glasses."

DISCOVER TEACHABLE MOMENTS IN THE CHILD'S DAILY LIFE

Must we always have to wait for a war or some other compelling but fortuitous event to capture the interest of children and to vitalize our health teaching? As long as health education is thought of in terms of formal health instruction, rich opportunities for

* Based on talk given at Wartime Conference on School Health Education, Hartford, Conn., January 18, 1944.

health education in school are lost. The school medical examination, vision testing of all children at periodic intervals, the luncheons children eat in school, and their many other activities have great educational value. They create attitudes; influence behavior; and leave, in most instances, lasting impressions because they are real life situations. They are teachable moments, and for the most part, we make no use of them in health education. Would many more youths have solved their medical problems long before the Victory Corps program if their previous school medical examinations had been planned as a real and vital experience? We know only too well the kind of school medical examination many of them experienced. They came through it like the boys in the Biblical story who passed through the fiery furnace—untouched! Certainly if the purpose of health education is to develop individuals whose knowledge and attitudes govern their daily living, then our most urgent task as health educators is to study opportunities in the school as well as in the child's out-of-school time to identify the teachable moments and see that they have positive value. This is not a new idea. But it has not yet influenced our school health procedures. The things we do to children and the things we endeavor to teach them in matters of health are for the most part unrelated. The classic and often-quoted illustration is the emphasis put on teaching hand washing in the schools, but not providing the children with facilities for hand washing in the school.

EDUCATIONAL IMPLICATIONS OF THE SCHOOL MEDICAL EXAMINATION

The educational implications of the medical examination are perhaps most evident. Yet there is an appalling waste of opportunity for health teaching in the hundreds of thousands of

routine school medical examinations performed in our schools every year. In spite of efforts to improve the quality of the school medical examination, in too many communities it still has only an imperceptible, positive current of health education, and in some places, the examination carries with it a highly shocking negative charge. Our children as a rule do not lack for medical examinations, but we fail to educate effectively in the process.

These are bad times to talk about improving the school medical examination. But it must be thought about and planned for now; otherwise, in 1960 we shall still be making speeches about the deplorable health of our youth as revealed by Selective Service examinations.

Suppose we could plan a school medical examination which would be an integral part of the child's education; how should we go about it? The impression made on child and parent in the course of giving the examination is most important. The educational and psychological effect of the school physician's and nurse's contact with the child is fundamental and obvious. One might think it unquestionably a conscious part of the school medical examination. Unfortunately, this is an essential part which has often been neglected. So much emphasis has been placed on finding defects that the child himself is overlooked. The late MacFee Campbell said that "the real child is more than an assemblage of organs plus a receptacle for school information. He is a complex bundle of highly organized instincts, emotions, and attitudes, and attention to these attitudes is more important than attention to his teeth."

PREPARATION IS NECESSARY

To make a favorable impression on the child and his parents, planning is necessary. The teacher, the nurse, and

the physician must understand the educational objective. Following are some of the ways this objective can be attained.

1. The teacher can discuss with the classroom the medical examination to prepare the younger children for their meeting with the doctor as a happy experience, and the older ones to ask questions, and to be prepared to act on any findings.

2. Where measuring of height and weight and vision testing are part of the classroom teacher's activities, these can be incorporated into her regular instruction.

3. Older children may assist with the testing procedures.

4. When the nurse does these tests, they should be discussed and interpreted to the teacher.

5. The nurse may furnish material which would be helpful in a classroom discussion of growth, seeing, and hearing.

6. A parents' meeting early in the school year may give the physician or nurse the opportunity to discuss the health service.

7. Parents should receive a special invitation to be present at the school examination. They should be informed of the date well in advance so they can plan to come. It will be necessary probably to send them a reminder the day before the event. The value of the parent being present is so obvious I do not think I need to elaborate.

MAKING THE EXAMINATION A TEACHABLE MOMENT

There should be a reasonable amount of privacy for the examination done at the school; the parent should have a definite appointment so as not to be kept waiting too long; doctor and nurse should be pleasant, and the child should be spoken to by his first name. These details may seem trivial, but they are essential, and they pay dividends in health education. Even today, when so many mothers are working, the attendance of mothers continues to be astonishingly high where attention has been paid to these details.

The examination should not only acquaint the mother with the significance of the defects found, and direct her on the pathway to treatment, but

also give the mother of the healthy child satisfaction and information. The physician may give advice on the child's diet, or hours of rest and study, or discuss the signs of a communicable disease which may be prevalent; or explain why it is important to keep a child at home when he shows the first signs of a cold; or give information and guidance on many other health matters. This face-to-face discussion with the physician, whether in school or private office, is both a rare and unequalled opportunity for health education.

The greatest good the young child may derive from the medical examination is a satisfying experience. By a patient, gentle manner, avoidance of threats or comments which create concern or confusion, and by telling each child something about his physical condition of which he can be proud, the physician will create in the child's mind a favorable impression of the examination. For older children, especially at the secondary school level, an explanation by the doctor of his findings and answering of questions, may equal in value the conference with the mothers of younger children.

The school medical examination is the occasion when the accepted medical authority can bring his influence to bear for good or ill. His influence operates through the manner in which he conducts himself with the child and parent, and by his interpretation of the results of the examination. The right approach can make the examination the cornerstone in the school health education program. It is only occasionally that the school medical examination *per se* makes a contribution to the child. It is what the child and his family *learn* from it that has long-term value.

TEACHER PARTICIPATION IN A MEDICAL EXAMINATION

The full educational implication of the medical examination will not be

realized unless the teacher can be made aware of the findings. A common method is to place a check mark on the academic record opposite the name of the part of the body which the doctor finds defective. Another way is to send the teacher a simple statement of the condition of each child and what she can do about any defects found. It would be ideal if the physician could talk with the teacher about his findings. Teachers should be given the opportunity occasionally to observe the school medical examination. This is necessary if the teacher is to have sufficient understanding of the procedure to prepare children for it through classroom instruction. In some schools, the physician has an occasional conference with teachers to exchange information. The school nurse can do this and does in many schools where there is very little school medical service. Through these contacts, the school doctor and nurse get valuable insight into the daily behavior of children, and the teacher gets information for health instruction and observation.

COÖPERATION BETWEEN EDUCATIONAL AND HEALTH GROUPS NECESSARY

Many may think that the program just described is impractical and beyond our means. We must not let present difficulties with respect to medical and nursing personnel cloud our vision of the future. We must think now about our child health services of tomorrow. They call for better understanding on the part of all those concerned with the school medical examination. They call particularly for local medical interest and leadership. Physicians are making some progress along these lines. The Academy of Pediatrics since 1941 has advocated this approach in the school examination.¹ Its Committee on School Health recently made recommendations which might guide boards of education in the selection of

well qualified physicians for school health service.² The American Public Health Association has recently approved a report on the Educational Qualifications of School Physicians, prepared by its Committee on Professional Education.³ Some state and county medical societies have recently given special attention to the school health program. The American Public Health Association last year organized a School Health Section. All these developments are promising. The medical and public health workers have a contribution to make in this area of school health. Likewise, they have much to learn from the educator about the educational values in the service they render. I am convinced that joint planning will result in vastly more effective medical examinations of the school child.

EDUCATIONAL IMPLICATIONS OF THE SCHOOL LUNCH

The war has given a new impetus to nutrition education. The school lunch offers perhaps the best real-life situation for nutrition education. This experience in the school can be the basis for life-long good eating habits. Moreover, if the school lunch program is approached from the point of view of its educational value, it can be an important factor in influencing the eating habits of the whole family. As in the medical examination, we have an opportunity to use a dynamic and realistic activity to develop habits, attitudes, and appreciations that can function outside of school. Whether a single supplementary dish or a complete meal is served, pupils may be given realistic experiences in selecting, preparing, buying, and selling foods. They may figure what foods may be served at a given price, and learn which offer the greatest nutritional value. They may consider the advantages and disadvantages of purchasing different quantities,

or share in deciding whether candies, carbonated drinks, cookies, and the like, are to be placed on sale. They will learn how wartime shortages affect the planning of the school lunch, and how they may assist in the war effort by preventing waste of foods and fats. They should become increasingly aware of all the problems that must be met in running the lunchroom, especially those which have to do with the nutritional needs of pupils. And, most important, children should learn to eat good food, and that requires good cooking.

DEVELOPING HOME AND SCHOOL COÖPERATION

Nutrition education, like the school medical examination, contains opportunities from which the family as well as the child can learn. The importance of including the family in our health education program was clearly revealed in that noteworthy study made by the New York State Department of Education of the everyday behavior of elementary school children.⁴ They found that, "If conflicts are to be avoided, no single groups, but all concerned, must work together to create an environment in which children can develop habits of work, play, and self-care, and have ample opportunity to practise them with satisfaction. This necessitates the participation of parents in the school program, and of teachers in the home program, as well as a community consciousness on the part of all." To work coöperatively with parents on the food and nutrition problems of their pupils, teachers need to become acquainted with parents—in their homes if possible—and also to keep them informed of what the children are learning. Whenever possible, in connection with every nutrition activity, it should be planned for the children to explain it to their parents, not only for the sake of keeping them informed, but because

the experience of explaining the studies to them helps to reinforce what the child has learned, and motivates further learning on the same subject. On occasion, mothers should be invited to visit the school to see demonstrations, and hear talks by the children, summarizing what they have learned in relation to nutrition.

FOR MORE MEANINGFUL HEALTH EDUCATION

I have used the school medical examination and the school lunch merely to illustrate their educational implications. There are similar opportunities for health teaching in other phases of the child's school, home, and community life. Children's needs, both of the "felt" variety, and those which also exist but of which children may be unaware, are the richest source. The medical examination, as we have said, can reveal some. But those in daily contact with children—parents, teachers, nurses—are best able to discover these needs by closer study of our children's daily lives. Their sleep and rest, their play and work, their food and eating habits, their manifestations of fatigue and mental health, are the substance of more meaningful health education. We must make this study if we are to teach health, so that, for the individual, health becomes an instrument or means for more effective living. And, finally, to succeed, we must learn how to enter children's lives. This means we must give more attention not only to what they do, but what they say, what they listen to; what they read; and what they write. We must learn to meet them on their own terms.

Today even a casual observation reveals situations calling for more effective health education in the lives of children as well as of their parents. Most children are getting less home supervision. Home accidents, especially to young children, are on the rise.

Some, living in strange and new communities under crowded and squalid conditions, are being neglected because of the absence of mothers on war jobs. Some already are orphaned as war casualties mount. Other children are burdened prematurely with work too heavy for their strength, and thousands are laying aside their school books to take full-time jobs. Venereal disease and tuberculosis have increased in the 15-17 year old group during the war period. The following accounts,⁵ written by high school students who worked during the summer months, illustrate some of the health and safety factors that enter into the work experience of young people:

"Last summer while I was working in a defense plant there were several things I did for personal safety and keeping physically fit.

"I worked in the mailing department as messenger and mail girl. I was constantly on the go, taking mail and telegrams on my route through the office and in the factory. While in the factory, the main thing I kept in mind was alertness at all times. Even though the electric trucks, which carry parts of machinery from one place to another, are in skillful hands, fatal accidents have happened.

"Comfortable shoes were a necessity on this job. The girls who wore high heels were usually very uncomfortable at the end of the day.

"Another thing I found out early in the summer, was that I couldn't sacrifice my sleep for shows and reading books. I found, if I went to sleep by 10 o'clock and got up by 6:30, I could do double my work if I had to, and there were days I did have to because of an absence.

"There was no shirking on lunches, either. In order to keep going until the end of the day I had to eat a good stable meal at lunch-time and a good-sized breakfast. My dinners were more on the light side. We had salads and fruits because of the warm weather.

"Regularities played a big part in my activities during the summer. I found I always felt fine and working seemed to be good for me mentally and physically."

Another high school student mentioned the long hours and insufficient

food in her farm experience. Her account indicates the need for better supervision of the student workers on farms:

"I worked on various farms this summer for three weeks. We usually went to bed very early (8:30 or 9:00), as we had to get up at 6 A.M. We found that going to bed late made getting up early very difficult. There was not much time for recreation, except on our day off, and I think we would have enjoyed working much more if we had had more free time.

"The food was rather poor. The only two things we really had enough of were bread and milk. I don't think I saw an orange more than five or six times altogether.

"There were no extra precautions taken against accidents, other than those we ourselves had enough sense to take, and no one seemed to care whether we were sick or well."

SUMMARY

This war offers an opportunity and a challenge to health educators. The challenge is to use this opportunity to discover: (1) how and why people learn; (2) to improve our methods and technics in health education. In war or peace, too frequently some other factor, not employed in our health education technic, provides the spark.

This riddle of learning may be uncovered by studying the child's twenty-four hour day. The child's eating and sleeping, his work and play, his habits of cleanliness and rest—in short, what he thinks and what he does—all those elements which govern the child's daily living should be searched for teachable moments. Need for this kind of educational approach is greater than ever today because of part-time employment, juvenile delinquency, the lessened stability, and the greater tensions in children's lives. Health education should have its roots in the child's dynamic experiences in the school, the home, and the community.

The school medical examination and the school lunch are two real-life situations which have rich educational impli-

cations. To achieve these values in the medical examination, physician, nurse, and teacher must plan the procedure as a learning experience for the child and the parent, who should attend the examination. The school lunch, complicated as its administration is today, has important opportunities for health education. The nutrition program can link the school and community with the home. If we are to create an environment in which children can develop habits of work, play, and self-care, and have ample opportunity to practise them with satisfaction now as well as in later life, it is necessary for parents to

participate in the school program, teachers in the home program, and there must be a community consciousness on the part of all.

Public Health Degrees and Certificates Granted in the United States and Canada During the Academic Year 1943-1944*

THE Committee on Professional Education of the American Public Health Association presents a report of public health degrees and certificates granted in the academic year 1943-1944. In addition, a summary of enrollments and degrees granted in the last five years is given. With the exception of public health nursing tables, the committee has included only graduate students enrolled in courses leading to graduate degrees and certificates. The basis for the record is the number of *students who received degrees* rather than the number of degrees granted in the specified period.

(Notes on page 1269)

¹ In all 30 universities the year's program of study in public health nursing approved by the N.O.P.H.N. is the major in a degree program. In 18 of the 30, a certificate is granted on completion of this major.

² These 12 universities do not grant certificates but the program of study in public health nursing which they offer is at least the equivalent of the certificate program.

³ Beginning with the academic year 1944-45, certificates will no longer be granted in these two universities.

⁴ Unable to estimate, since students do not take the program of study in one block.

⁵ Only students who already have a B.S. degree are eligible for a certificate in public health nursing upon completion of the program of study.

Seventy-five Years of Public Health in Massachusetts

RAYMOND S. PATTERSON, PH.D., F.A.P.H.A., AND
MARY CARR BAKER

*John Hancock Mutual Life Insurance Company; Massachusetts Department of
Public Health, Boston, Mass.*

MILITARY historians tell us that the battle of Chickamauga just happened. This engagement, one of the bloodiest of the Civil War, was fought because the commanders of the northern and southern armies knew of the existence of springs of pure water there, but neither was aware of the nearness nor the intent of his adversary. In many ways sanitary considerations markedly altered the outcome of the war, and a tragic proportion of soldier deaths was due to diseases and infected wounds. The realization of the pressing need for improved sanitary services carried over from military experience to civil life.

Within five years of the close of the War Between the States, the Massachusetts Legislature had passed an act to establish a State Board of Health—the first in America. The act of 1869 directs that:

The board shall take cognizance of the interests of health and life among the citizens of this Commonwealth. They shall make sanitary investigations and inquiries in respect to the people, the causes of disease, and especially of epidemics, and the sources of mortality and the effects of localities, employments, conditions and circumstances on the public health; and they shall gather such information in respect to those matters as they may deem proper, for diffusion among the people.

Considering the lack of scientific knowledge of that day, these broad authorizations have about them a sur-

prisingly modern ring. Pasteur had disproved the older theories of spontaneous generation but his bacteriological discoveries still were concerned with diseases of wine and silkworms: they had yet to reach the realm of human health. Scientific thought was still cluttered with Pettenkofer's beliefs linking emanations from moist soil and tuberculosis. It was still the era of bad smells—"If anything is settled as to the causes of disease, it is the influence of decomposing organic matter in giving rise to . . . typhoid fever . . ." wrote the Secretary of the new Massachusetts Board.

The first annual report of this pioneering Board is so realistic that one can almost attend the inaugural meeting. The Governor had appointed the membership promptly. The senior appointee, Dr. Henry Ingersoll Bowditch, calls the members together. They are meeting in a committee room, for no quarters are provided. Fully conscious of the import of this unprecedented occasion and of the solemnity of the moment, Dr. Bowditch arises to read his charges to them:

The law requires us to diffuse among our people any already established laws of public health, and also whatever we may hereafter discover on that subject. . . . How shall we diffuse this knowledge? . . . (a) By lectures from our Secretary or from members of the Board on various special subjects connected with public hygiene—such as ventilating, and

building, and location of houses; on various well-known diseases capable of partial or entire prevention on knowledge of causes being given. . . . (c) By the publication in a compact form and the wide circulation of the pith of our general knowledge on public hygiene. . . . (d) By our annual reports to the legislature, which, I trust, will always be models of brevity and of compact learning.

A week after this auspicious beginning, the Board came together again to adopt by-laws. At this meeting the following subjects were singled out for special investigation by the members: prevailing modes of slaughtering, sale of poisons, comparison of the sickness and mortality in different kinds of houses occupied by the poor. In addition, it was then and there decided to address a circular letter to the local boards of health about their powers and duties, and further to collect and publish the number and prevailing causes of deaths in the most populous cities and towns.

A PIONEERING DECADE

Throughout the first ten years of its existence, the members of the Massachusetts Board of Health carried on ingenious investigations concerning the nature of the sanitary problems confronting the state and the means which might be effected to remedy them. Merely the record of the activities of these inquiring minds is an inspiration to us in these settled times. One of the first subjects which attracted the attention of the Board was the method employed in slaughtering and the disposal of animal refuse in the nearby town of Brighton. Fifty-odd small companies carried on slaughtering, under sanitary conditions which beggared the descriptive powers of the not inarticulate investigators. The Board sought courageously to compel the erection of sanitary abattoirs which might mitigate the worst of the unspeakable nuisances. That the job needed doing, there was no question, but the members struggled

with their consciences because they could find no evidence in the death records of Brighton to support their beliefs that the dreadful smells coming from the slaughter houses must be inimical to health.

Among their early activities, the Board subsidized the investigation of the sanitary condition of inland waters by the best qualified engineers of the day. Their reasonable interest in the pollution of ponds and streams used for potable water supplies was admixed with a curious concern about mill-dams and other obstructions which raised the water level of the surrounding soil, causing it to give forth noxious vapors and vague but insalubrious emanations.

As a practical means of ascertaining the state of the public health, the Board circularized the cities and towns asking that a physician be designated to act as a correspondent for the community. From the returns, conscientiously made, the Secretary ascertained not only the existence and nature of any epidemics, which the Board proposed to take steps to suppress, but the Board learned from the correspondents as well the prevailing opinions about the nature and causes of the diseases which plagued their communities. Though their democratic acceptance of majority opinion as medical gospel amuses us in these smug days of scientific research, one by-product of this correspondence was the beginning of a productive coöperation between the state and local health authorities.

This pioneering period was dominated throughout by Dr. Henry Ingersoll Bowditch, long an authority on consumption. In his sixtieth year and firm in the belief that, where ground is damp, consumption develops, he had at the same time the vision and the breadth of understanding to mold and direct all the variety of activities which then made up public health practice. After ten years his productive work was

ended by the unhappy amalgamation of health with lunacy and charity. In explaining his resignation in protest against this impractical act, Dr. Bowditch wrote:

In 1878 came mutterings of political disaster to the ruling powers, and forebodings of what the renowned General Butler would do with the numerous "commissions" (that of health among them) that were "spending wastefully the people's money." Accordingly, to attack this redoubtable General upon his political "flank," the legislature, under suggestions from Governor Talbot, merged the three departments of Health, Lunacy, and Charity, a Cerebrus, in fact, in its grotesqueness of head. Three commissions, all different in ideas and modes of action, jumbled into one heterogeneous mass, simply because the ruling party feared the advent of power of a political adventurer! . . . At one time, for three or four successive meetings, nothing was done about sanitation, the time being occupied in discussions on lunacy and charity, on both of which subjects, so far as they had relation to the State, neither I nor my comrades on the old board knew anything.

Although public health languished when it was linked with such unrelated state activities, the investigation of streams and ponds continued and some sanitary progress was made. One compensation for the loss of this vigorous-minded pioneer was the emergence of a man of like caliber, Dr. Henry Pickering Walcott, who served first as health officer and later as chairman of the health subcommittee of the triple-functioned board. When the unfortunate union was ended and a new and greatly revitalized board appointed, Dr. Walcott was made its chairman, a position which he held for almost thirty years, until the Board was reorganized as a department.

THE "GOLDEN AGE" OF PUBLIC HEALTH

The phenomenal scientific advances following in the wake of the discoveries of Pasteur and Koch came to full-flowering in Massachusetts under Walcott's forceful leadership. Bowditch had pointed the way; Walcott built the

solid foundation for effective public hygiene. He rallied about him young men who were to make Massachusetts the proving ground of health administration. Early in this productive period, an experiment station at Lawrence was established, and from it has come much of the world's knowledge of scientific water and sewage treatment. A laboratory was set up in cooperation with Harvard University for the production of antitoxins and vaccines which has supplied the state to this day with the means of saving lives and preventing epidemic diseases. Epidemiological procedures were inaugurated which are still used in controlling outbreaks of disease.

To implement the state-wide control of communicable diseases, regional inspectors of health were appointed to act as advisers of local boards of health, the first example of this extension of state service in our country. During this golden era many young men began their scientific careers in Massachusetts—a few to stay on to lead the several health services of the State Board, many more to go out to carry the torch to the nation. On the staff of the Board during this period will be found the illustrious names of Theobald Smith, Sedgwick, Rosenau, Goodnough, Hazen, Fuller, Stearns.

New times call for new methods. The varied administrative burden had become too great and the responsibility too heavy to be carried on the anonymous shoulders of a board, however capable the members might be. The needs of the day called for the creation of a responsible commissionership and, by the law of 1914, the old board was dissolved and a health department created to supersede it. Full of honors, Dr. Walcott retired.

DRAFT REVELATIONS CALL FOR NEW HEALTH SERVICES

Once again, in a time of crisis,

vigorous leadership was forthcoming. A surgeon of the U. S. Public Health Service, Allan J. McLaughlin, was assigned to be commissioner of the newly reorganized department. The council appointed to advise him was composed of competent and disinterested medical and lay members. The division heads were men of proved administrative ability. Providentially, there was thus brought together a working team competent to deal with the health needs startlingly revealed by the first World War draft. Under this wholesome influence, the Massachusetts Department of Health again pointed the way during, and following, the tumultuous days of the first World War.

After four productive years, Dr. McLaughlin was recalled by the Public Health Service to undertake a war assignment and Dr. Eugene R. Kelley, who had proved his mettle as Director of the Division of Communicable Diseases, was appointed to succeed him. After his untimely death, he was in turn succeeded by his deputy, the brilliant Dr. George H. Bigelow. Under these three dynamic men the department took on new functions and turned its face in new directions.

In addition to the classic interest in environmental sanitation and communicable disease control, new undertakings in personal and community hygiene were introduced by these men. The departmental program was broadened by the assumption of services for the prevention and treatment of tuberculosis, the addition of new specialties in maternal and child health, public health nursing, nutrition, and school and adult hygiene. During part of his working hours, the sanitary officer was induced to shed his badge of law enforcement in order to adopt the gentler rôle of guide and mentor. All the ad-

venture of pioneering in public health was not yet gone.

This was the period of national economic ups and downs. It included a sharp but cruel post-war depression, the "permanent prosperity" of the "twenties" and the debacle of the early "thirties" which was to give us social security, with its stimulus for adequate national health administration. To the states this meant federal grants for greatly enhanced programs in maternal and child health, crippled children, venereal diseases, and tuberculosis.

SELECTIVE SERVICE PROVIDES ANOTHER SAMPLING OF AMERICA'S HEALTH

The exigencies of a nation geared to war conditions have imposed upon state health departments generally many new and specific obligations. Among its other programs the Massachusetts agency is administering special case finding projects in tuberculosis, state-wide diagnostic and social services for cancer and other chronic conditions, applied nutritional and dental hygiene programs—services which may be far-reaching in their ultimate social consequences. Typical of these new activities is the Emergency Maternity and Infant Care Program which furnishes obstetric and pediatric services free for the wives of soldiers and sailors within certain pay grades, a medical care project under the supervision of the department.

Despite the complications which new activities inevitably entail, we find the Massachusetts Department seeking by the expansion and development of its district offices, and by means of demonstration, encouragement and supervision to strengthen rural and suburban health organization to the point where local boards themselves may meet their own obligations.

A Sponsored Epidemic of Mumps in a Private School

MILTON I. LEVINE, M.D., F.A.P.H.A.

New York Hospital and the Department of Pediatrics, Cornell University Medical College, New York, N. Y.

AMONG the so-called contagious diseases of childhood, mumps has one quality peculiar to itself—that of being less severe in complications before puberty than after this period. Although occasional cases of mumps encephalitis are encountered among children, other complications such as orchitis, ovaritis, and pancreatitis are rarely seen under 12 years of age.

From a public health and especially from a military standpoint, the problem of preventing mumps is of great importance, for, next to venereal diseases, mumps is reported as the most disabling of all acute infections among army recruits.¹ During the first World War, nearly 4,000,000 man days were lost from duty in the U. S. Army because of this disease.²

It might seem reasonable, therefore, in view of these facts and figures, to attempt to expose children to cases of active mumps in order that they might develop an immunity prior to the onset of adolescence.

The present paper reports the results of such an attempt in a private school of 161 children during the mumps epidemic in New York City in the early months of 1942. This school* had for the twelve previous years been remarkably free from mumps. On a number of occasions the spread had been pre-

vented either by isolation of exposed children or by partial quarantining of the class, viz.: treating the class as an isolated unit in school, and isolation from other schoolmates before and after school hours. As a result of these procedures only a very few children in the graduating classes gave a history of having had mumps, whereas many cases developed among graduates while attending high school or college.

On January 22, 1942, one of the children (E.S.) developed mumps, exposing not only those in her own class (Group VIII)* but also her brother and two other children from Group XI who were visiting at her home. Four days later (January 26, 1942) another child (H.M.) in Group VIII also developed mumps, not only re-exposing the class but exposing a brother in Group IX, a friend in Group IX, and another brother in Group XI.

Under usual routine methods Group VIII would have been kept as a unit in the school, coming late and leaving early, and remaining isolated from other children in the school. The other 6 known exposed children would have been withheld from school until the period of incubation was over.

However, the following letter was sent immediately to all parents:

* The children at the City and Country School are grouped by ages (i.e. all 8 year olds are in Group VIII, etc.).

* City and County School, New York City

Dear Parents:

At the present moment there are a number of cases of mumps in the school. Several of the children have brothers or sisters in other classes not exposed.

With all other contagious diseases our policy is to exclude these children exposed at home to avoid further possibility of contagion.

However, since mumps is an extremely mild disease and almost devoid of any complications before puberty, and may be at times very painful and result in serious complications after puberty, I feel it would be inadvisable to do anything to avoid exposure to this disease, unless there is a particular reason.

We would like to know if you and your child's physician are in agreement.

This letter brought forth the unanimous approval of the parents, with only one questioning note from a pediatrician who felt that no child should ever knowingly be exposed to a disease, but consenting to the plan if most of the parents agreed.

Accordingly, no restrictions were placed on exposed children, with the exception of the classes of children aged 3, 4, and 5 years. Within 3 weeks, 14 cases of mumps had developed in 5 different classes, 12 of which were directly traced to the two children with the original infections.

The spread continued and within a period of 3 months 62 children (54.4 per cent) from a total of 114 susceptibles in the upper 8 classes developed the disease. Four children in the lower 3 classes contracted the disease from their brothers or sisters. These children were excluded from their classes during the incubation period and no further cases resulted. The distribution of infection in the various classes is shown in Table 1.

Of the 66 children who developed the disease, 6 developed complications. The first two generations of the infection were mild and all 16 cases recovered without complication.

However, in the third generation of 18 cases there was 1 case of mumps

encephalitis, and in the fourth generation of 19 cases there were 3 cases of mumps encephalitis. Two of the children who developed encephalitis received spinal taps as corroborative evidence, although all four suffered severe headaches, vomiting, and neck rigidity at the end of the first week. The parents of the children developing mumps encephalitis were reassured that there would be no aftereffects.*

Two other complications which developed were a moderately severe orchitis in a boy, aged 12, and a possible pancreatitis in a child of 8 years.

When the epidemic subsided in April, 1942, a questionnaire was sent out requesting complete information on the children who contracted the disease, with an added question as to whether any other members of the family contracted the disease. The final analysis revealed that beside one teacher, who was incapacitated with the disease for 2 weeks, 10 parents suffered from the infection, a possibility which was completely overlooked when the plan was suggested.

It is doubtful if any further epidemics will be sponsored by the school.

Total	148	66

* These 4 cases were exposed to brothers and sisters in higher classes. They were withheld from school during the incubation period, thus preventing further spread in their classes.

* This opinion was corroborated by consultation with Dr. Josephine Neal of the New York City Department of Health.

SUMMARY

1. With the consent of the parents, a mumps epidemic which could have been limited was sponsored in a private school of 161 children.

2. Out of 114 susceptible children exposed, 62 contracted the disease within a period of 3 months.

3. Of the 62 children developing mumps, there were 6 who developed complications.

There were 4 cases of mumps encephalitis, 1 case of orchitis, and 1 with a probable mild pancreatitis.

4. One teacher and 10 parents also developed mumps.

Salmonella Types Isolated in Georgia in 1941-1943, Including a New Type—*Salmonella georgia*

JANIE F. MORRIS, ALICE BRIM, AND
T. F. SELLERS, M.D., F.A.P.H.A.

Georgia Department of Public Health Laboratories, Atlanta, Ga.

AN increasing number of *Salmonella* strains is being isolated in the laboratories of the Georgia Department of Public Health. In the 3 year period, 1938-1940, our laboratories made only 47 isolations of *Salmonella* organisms from blood and stool cultures. During the succeeding 3 years, 1941-1943, 130 isolations were made. This increase is probably due to more efficient methods of isolation and identification rather than to an increase in incidence of the infections.

Bismuth sulfite agar and Bacto-SS

agar for plating, tetrathionate broth for enrichment, and Kligler's iron agar for colony differentiation, have proved a satisfactory combination of media for isolating the organisms. A fairly adequate assortment of group and specific antisera further facilitates identification. However, for the past 3 years most of our strains have been either identified or confirmed by the New York Salmonella Center, Beth Israel Hospital, New York, N. Y. During this time 20 different types have been encountered, including a new type.

Some types were isolated only once while others occurred more frequently. *Salmonella bredeney*, *S. bareilly*, *S. georgia*, *S. litchfield*, *S. sendai*, and *S. give* were each represented by a single isolation from only 1 patient. *S. tennessee* was isolated twice from 1 patient, and *S. muenchen* 3 times from another. *S. paratyphi B*, *S. typhimurium*, and *S. choleraesuis* accounted for 53.8 per cent of all isolations. A list of the types found in this state during 1941-1943 is presented in Table 1.

S. paratyphi B and *S. choleraesuis* were found in 59 per cent of the blood cultures. One strain of *S. choleraesuis* was isolated from pus from the knee. A combination of *S. typhi* and *S. montevideo* occurred in a 3 year old child. *S. typhi* was recovered from the first stool culture. From a second specimen received 5 days later, both *S. typhi* and *S. montevideo* were isolated. Table 2 shows the distribution of types in blood and stool cultures.

There have been very few instances in which relationship between the

cases could be established. One outbreak of food infection due to *S. typhimurium* occurred in an institution for boys. There were about 40 patients who had symptoms of fever, vomiting, and diarrhea. Unfortunately, the peak of the epidemic had passed before the laboratory was called upon for assistance. Stool specimens were received from only 6 patients and *S. typhimurium* was isolated from 4. Four *S. paratyphi B* infections occurred in the staff personnel of a small hospital. The first case, a nurse, was proved by a positive blood culture. About 2 months later 2 other nurses became ill with nausea, vomiting, diarrhea, and temperature elevation to 103° F. No blood or stool cultures were made at the time. Later, the chief physician was taken ill with about the same symptoms, and a blood culture was positive. Epidemiological investigation indicated that the only source of food common to the physician and nurses was milk and cream. A milker in the dairy that supplied milk to the hospital was found to

* One isolation was made from pus from knee.

be a carrier of *S. paratyphi* B. Two cases due to *S. panama* occurred simultaneously in adjoining homes. There were 2 cases due to *S. anatum* in 1 home, the mother and daughter being ill at the same time.

S. typhimurium, *S. derby*, *S. bareilly*, *S. oranienburg*, *S. litchfield*, *S. give* and *S. anatum* were isolated from feces in routine food handler examinations.

The new type, designated as *S. georgia*, was isolated from the feces culture of a 16 year old white boy during a routine examination of food handlers. The boy apparently was a healthy carrier. The organism was identified by the New York Salmonella Center and confirmed by Dr. P. R. Ed-

wards of the National Salmonella Center, Lexington, Ky. It has the antigenic formula VI, VII: b-e,n,z₁₅.

SUMMARY

During the 3 year period, 1941-1943, 20 types of *Salmonella* organisms were isolated from blood and stool specimens. Of 130 isolations, *S. paratyphi* B, *S. typhimurium*, and *S. choleraesuis* accounted for 53.8 per cent. *S. paratyphi* B and *S. choleraesuis* were found in 59 per cent of the 44 positive blood cultures.

A new type, isolated from the stool of a normal food handler, has the antigenic formula VI, VII: b-e,n,z₁₅, and has been designated as *S. georgia*.

Isolation of *Shigella paradysenteriae* Type P288 of Boyd from a Case of Acute Diarrhea

JANIE F. MORRIS, ALICE BRIM, AND
T. F. SELLERS, M.D., F.A.P.H.A.

Georgia Department of Public Health Laboratories, Atlanta, Ga.

DURING June, 1944, several cases of acute diarrhea occurred among trainees at a naval training school for WAVES located in Georgia. All patients had temperatures of 102-103° F., profuse watery stools, abdominal cramps and prostration. The duration of illness was 3 to 4 days. Fecal specimens from only 2 patients were submitted for culturing. From 1 of these was isolated an organism identified as *Shigella paradysenteriae* P288,* a type

described by Boyd^{1,2} as occurring in India. This isolation, to our knowledge, is the first to be reported in this country.

The incitants of bacillary dysentery comprise a group of Gram-negative bacilli having diverse characters and a study of both biochemical and serological properties is essential to their identification. Boyd¹⁻⁴ has made valuable contributions to the study of dysentery bacilli and has shown the Flexner group to be of complex antigenic structure. An analysis by Boyd² of the antigenic structure of 4,856 strains of

* Identification was confirmed by Dr. A. J. Weil, Lederle Laboratories, Inc., Pearl River, N. Y., and by Dr. K. M. Wheeler, Connecticut State Department of Health Laboratories, Hartford, Conn.

"mannitol-fermenting bacilli (except late fermenters of lactose and sucrose) isolated in military laboratories in India in the years 1932-1935" revealed a number of strains which gave the biochemical reactions of the Flexner species but which were antigenically different. This atypical group was subdivided into several distinct types, one of which was designated as P288. According to Boyd² and to Wheeler⁵ P288 has a specific antigen and very little if any Flexner group antigen. Boyd⁴ states that "P288 . . . is very definitely a true dysentery bacillus."

P288 cannot be distinguished from other members of the *Shigella paradysenteriae* group except by serological reactions. The organism isolated by us fermented dextrose, mannite, and arabinose and gave negative reactions with lactose, sucrose, salicin, adonitol, dulcitol, xylose, and sorbitol. Trehalose and maltose showed delayed reactions. Indole was not produced. The organism was agglutinated by P288 antiserum only.

Of the 4,856 strains studied by Boyd,²

64, or 1.3 per cent, were type P288. In 1936 Wilson⁶ reported a small outbreak of dysentery due to P288 which occurred in the Indian platoon of a British regiment in Burma. Ten cases occurred, and P288 was isolated from all 10. Although, so far as we know, the case described here is the first to be reported in this country, a critical study of the antigenic structure of so-called "inagglutinable Flexner" strains may show this type of *Shigella* to be more prevalent than has heretofore been suspected.

LAURELS FOR MASSACHUSETTS

THE sixth of December is a day of celebration for public health workers in Boston; and it is a day of significance for the movement throughout the United States. The Massachusetts State Department of Health on that date commemorates the 75th anniversary of the department, and the 50th anniversary of the establishment of its State Antitoxin Laboratories.¹

Only New York City can perhaps compare with the State of Massachusetts in the significance of its historical contributions to the cause of public health on our continent. This "Commonwealth" established in 1869 not only the first of our state health departments in point of time but—for many decades—the first in point of quality. Chapin's survey of 1915 scored Massachusetts 745 and New York (the next state in rank) 730. Massachusetts still stands among the top health departments of the United States.

The establishment of the Lawrence Experiment Station in 1886 laid the basis for all modern practice in sewage disposal. The Annual Report of the Department of Health for 1892 presents studies which are still classics in the field of epidemiology. The State Antitoxin Laboratory has been a model of service and a center of research since 1894. The names of Theobald Smith, of William T. Sedgwick, of Hiram F. Mills and G. W. Fuller and Allen Hazen and E. O. Jordan shed luster on the early history of this unique organization; and, in recent years, Massachusetts has continued to pioneer in its comprehensive programs for the control of tuberculosis and cancer.

We congratulate the public health profession of Massachusetts on its glorious past and we look to it for continued leadership in the future.

PSYCHIATRIC SERVICE FOR THE RETURNED VETERAN

AT the meeting of the American Psychiatric Association last spring, it was announced that the objectionable label "psychoneurotic" had been dropped from the records of selectees rejected for nervous and mental conditions and replaced by the phrase "not suited for military service." This is a sensible designation, much more accurately describing the facts, since many individuals unfitted for the intense emotional hazards of modern warfare will prove successful, and often superior, members of a civilian community.

The fundamental fact remains, however that, according to Colonel L. G. Rowntree of Selective Service, between thirty and forty per cent of rejections and discharges have been related to mental and nervous status and that the total number of persons of this type in the rejected and discharged groups combined will exceed two million.

So far as discharges are concerned, the Veteran's Bureau will no doubt provide institutional care for those in need of such treatment. The great majority of both rejected and discharged groups will, however, need outpatient care alone; or outpatient care subsequent to hospitalization. The urgent question before us today is how and where this outpatient care shall be provided; and there are three major alternatives. Shall mental hygiene clinic provision be made as a special service for discharged soldiers under the direction of Veteran's Bureau hospitals? Shall it be made through community mental hygiene clinics serving all persons in need of this special type of care? Or shall it be developed as an expansion of the outpatient service of general hospitals?

It seems reasonably clear that the first of these three alternatives is least desirable. The development of new outpatient clinics under the Veteran's Bureau would involve serious duplication in a field where concentration of effort is essential. Furthermore, the treatment of the discharged soldier in such clinics would tend to label him as a special type of military psychoneurotic whereas he is essentially the same kind of individual as the rejectee for mental and emotional causes and as the ordinary civilian with similar difficulties. The strain which has accentuated his problem is different; but the task of adjustment to civilian life is the same.

On the question whether we should build increased mental hygiene service on independent mental hygiene clinics or on the outpatient services of general hospitals, Dr. J. M. Cunningham of the Connecticut State Department of Health has presented a challenging argument.¹ He points out that in addition to the men who have received various psychiatric labels at the hands of induction boards or service doctors, there is another large group in which emotional and physical defects are closely interrelated in what are now classed as psychosomatic disorders. Dr. Cunningham believes that the "integration of psychiatry and medicine may be expected to be the next great development in the application of psychiatric knowledge." Therefore, all "psychiatric service for adults should be organized as a part of the general hospital and it should be integrated with the other medical services for both in and out patients." He suggests that there should be appropriations to subsidize psychiatric diagnosis and treatment in the general hospital for both inpatient and outpatient work; that this service should be on a full-time paid basis utilizing psychiatrists, psychologists, and psychiatric social workers; and that such services should provide for veterans along with all other adult members of the community.

In states where a well organized state department of mental hygiene has been developed, the provision of community mental hygiene clinics might be conceived as a logical function of such an organization; but it should be remembered that the problem presented is not that which the ordinary state mental institution is geared to meet. The psychoneurotic individual is only rarely an incipient psychotic patient but quite a different type of person; and one who will more readily turn to a community hospital than to a clinic operated by an institution for the insane. The problem is a complex one and will not be susceptible of any general uniform solution. There is, in any case, much force in Dr. Cunningham's emphasis on the importance of psychosomatic medicine; and the plan he proposes embodies the type of decentralized and generalized service which is coming to the forefront in public health practice. Possibly clinics directed by mental hygiene departments or health departments could be organized as joint enterprises in coöperation with general hospitals.

The problem deserves the serious consideration of mental hygienists and hospital executives and of health officers—as representing general community interests in health planning.

THE NO-MAN'S LAND OF THE SMALL INDUSTRY

ONE of the most interesting sessions of our last annual meeting dealt with the admirable program for health education of industrial workers developed in the Fort Greene area of Brooklyn. Such a program, however, depends for its efficacy upon the availability of the actual health services for which health education prepares the way. There is little gain in teaching the worker about the control of tuberculosis if the air of his shop is laden with silica dust; or in emphasizing the value of health examinations and prompt treatment of disease if doctors to make these examinations and supply this treatment are not at his disposal.

We have no comprehensive knowledge of recent developments in the field of industrial health service. Just before our entry into the war, the Council on Industrial Health of the A.M.A. presented an illuminating study of the situation at that time.¹ This study cited results which are tabulated below:

<i>Size of Plant</i>	<i>Number of Plants</i>	<i>Number of Employees</i>
Less than 100 employees	143,615	2,260,956
100-500 employees	13,656	2,885,670
500-1,000 employees	1,660	1,333,323
Over 1,000 employees	978	2,262,282

A survey of a sample group of plants made by the Council showed that in the group of very small plants (less than 100 employees) none had a full-time physician and only 3 per cent had an industrial nurse. Of the small plants (100-500 employees) only 18 per cent had full-time medical service and only 19 per cent full-time nursing service. In the medium-sized plants (500-1,000 employees) 21 per cent had full-time medical service and 52 per cent full-time nursing service. In the large plants (over 1,000 employees) 47 per cent had full-time medical service and 85 per cent full-time nursing service. If we assume that the sample

studied was representative, 79 per cent of all the industrial workers in the country had no full-time industrial medical service.

Bloomfield and associates, in a survey conducted by the U. S. Public Health Service,² reported that in establishments with over 100 employees, 20.3 per cent of the workers had the services of a full-time plant physician and 27.6 per cent those of a part-time plant physician; while in establishments with less than 100 employees, the comparable figures were only 0.4 per cent and 5.6 per cent, respectively. A report of the National Association of Manufacturers³ showed that in establishments with less than 250 employees only 13 per cent of the plants studied even had a physician in the plant at regular scheduled hours.

A more recent study of 565 industrial establishments in New York City⁴ gave even more discouraging figures. Of 11 plants with over 250 employees (total employment, 12,373), 45 per cent had full-time medical service and 64 per cent had full-time nursing service; but of 554 plants with less than 250 employees (total employment, 12,470), not one had a full-time physician and "practically none had any nursing service whatsoever."

We talk optimistically about progress in industrial medicine; but the fact is that about half our total working population is in small plants which have practically no effective service of this kind. Even of the workers in medium and large plants only about half have full-time medical service, so that not over a quarter of the total industrial population is adequately provided for.

We may reasonably hope that the larger plants have learned during the past three years the values of industrial health and will provide such service for themselves after the war. But, what can be done about the small plants?

The only possible way in which such plants can be supplied with the constructive health program which they need is by common services for groups of five, ten, or twenty such establishments. To expect that small industries will voluntarily combine on their own initiative to obtain such services is fantastically wishful thinking. There must be leadership. From what source can this leadership come?

In communities where there is a medical school or a school of public health, the initiative might come from that source (as has been demonstrated on a small scale in one particular instance). In most areas, the health department is the only really practical source of leadership.

The *Journal of the A.M.A.*, in discussing the report of the Council on Industrial Health, cited above, said, "When it is found possible to extend qualified preventive medical assistance to such concerns (small plants), through the joint agencies of private practice and public health administration . . . an achievement will have been recorded in which all elements in the medical profession can take lasting satisfaction."

Is there not here an outstanding opportunity for the local health officer who desires to render constructive service to his community?

In undertaking such a project, the first step would be the formation of a local committee including representatives of local industries and of the local medical society to study the problem. Such a study would, first of all, reveal the need for expert industrial hygiene counselling with regard to shop sanitation, control of industrial hazards, and the development of a comprehensive health program in small plants—more detailed and intensive than can be supplied by the state department of health. Local industry would quite certainly support appropriations for a trained industrial hygienist on the health department staff

to provide such guidance. Next, the need would emerge for preemployment and periodic health examinations and for industrial nursing service. A plan for providing these services could next be formulated, utilizing private practitioners of medicine and local visiting nurse organizations so far as possible but under the unified direction and supervision of the health department—for without direction and supervision no program can function effectively. Finally, the problem of remedial care would have to be faced—to be provided by the local medical profession under some plan of prepayment which would insure adequate service to the patient and adequate remuneration for the physician.

How far such a program would go in a given community would depend on circumstances and on psychology. We feel sure, however, that the health officer who will take the first step of a survey of local conditions (in coöperation with industry and with the medical profession) will open the door to one of the most vital services any health administrator can render—the bringing of the benefits of modern industrial health service to that half of our employed population which works in the No-Man's Land of the small plant.

THE PLACE OF PREVENTIVE MEDICINE IN THE MEDICAL CURRICULUM

THE Conference of Professors of Preventive Medicine, held at the time of our New York meeting, staged an interesting discussion on the rôle of courses in preventive medicine in the education of the physician. It was generally agreed that "Public Health" is a field for postgraduate training but that "Preventive Medicine" is an essential part of the training of the medical student. An important point was raised, however, by speakers who contended that this subject might well be taught as a part of other courses and not as a separate item in the curriculum.

Clearly this is a counsel of perfection. The day may come when personal hygiene is taught as a part of physiology and when the clinical branches of medicine are developed not only from a *preventive* aspect but also with a view to that *constructive* medicine which visualizes the ideal of health in a positive sense as the goal of the physician. Were such ideals generally realized (as they are today in some pediatric faculties), no separate department of "preventive medicine" might be needed. That day, however, is far in the future.

Even in such a Utopian situation, there is one basic element which it would be essential to add to the curriculum. Nowhere (except in "preventive medicine" or "public health") does the medical student receive instruction in the basic and fundamental influences on health of the physical and social environment. When the work of the clinical years has become thoroughly permeated with a preventive and constructive viewpoint, there will still be need for a special course (perhaps preclinical) in Environmental Therapeutics, covering the influences of

sanitation and of the community machinery and social factors influencing physical and emotional well-being. This is a subject quite as important as *Materia Medica*.

Finally, in considering the basic problem of arousing in the medical undergraduate a really vital interest in prevention, we should not forget the obstacles placed in our way by the present economic basis of medical practice. So long as the doctor is paid on a fee-for-service basis, his income and his opportunity for service must depend on the treatment of disease, since he will be called in only when something hurts. The medical student subconsciously realizes this fact and inevitably feels that prevention, if not hostile to his interests, is at least irrelevant to them. Only when the doctor is habitually employed on a prepayment basis for health service will preventive and constructive medicine really become vitally significant.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted.

Introduction to Public Health—
By Harry S. Mustard. (2nd ed.)
New York: Macmillan, 1944. 283 pp.
Price, \$3.25.

This book is a good standard text for the college student. It is also suitable for the first course given to the student of nursing, dentistry, or medicine.

The author has been skillful in boiling down such a comprehensive subject into 283 pages and still finding room for important details. Basic principles and trends are frequently referred to. The longest chapter contains 61 pages on The Acute Communicable Diseases. Seven pages are devoted to toxoid, antitoxin, and various other aspects of diphtheria, while one interesting and up-to-date page covers Rocky Mountain Spotted Fever. The subject of Sanitation is condensed into twenty pages. The brief mention of septic tanks is hardly in proportion to the rural health officers' headaches. There is no separate mention of the sanitation of eating places or of organized health education for food handlers.

The two new chapters added since the first edition are on the subjects of Industrial Hygiene and Medical Care. The eight pages on Industrial Hygiene bring out the relationship between workmen's compensation laws, industrial accidents and diseases, and the efforts of industry. The cost of the industrial hygiene program, estimated at \$10 to \$15 per year for each person employed, "must prove itself to be a good investment if the businessmen concerned are to engage in or continue it." In the new chapter on Medical Care the author quotes from the National Health Survey and other reports regarding the prevalence of dis-

abling illness and the cost of medical care. The controversy as to government participation is clearly and objectively described. The paragraph, "Some Deterrents to a Wise Course" is admirably stated.

This book contains 16 tables but no illustrations. It has a good index. Two thousand items are listed.

V. L. ELLICOTT

Postwar Planning in the United States: 3. An Organization Directory—
New York: Twentieth Century Fund, 1944. 34 pp. Price, \$1.00.

This Directory is the third in a series of surveys made by the Twentieth Century Fund, revealing that these post-war planning groups have increased from 105 in 1942 and 137 in 1943 to nearly 200 in 1944. Thirty-nine are government and 158 are private agencies. Seventeen of the total are in the welfare and health group. A brief digest is presented of the background, activities, and personnel now engaged in post-war planning under each agency. The Directory can be recommended for its inclusive character. Each agency doing post-war planning should be aware of other agencies concerned with the same field.

REGINALD M. ATWATER

Stay Young and Live—
By J. Clarence Funk, Sc.D. Richmond, Va.: The Dietz Press, 1943. 125 pp. Price, \$1.75.

This book is by the Director of Education, Virginia State Department of Health. It has a foreword by the late Claude C. Pierce, M.D., U.S.P.H.S. (ret.).

The state of mind of the author of

this book is revealed by his happy choice of 28 chapter headings. Although he discusses common, everyday subjects, he dolls them up. Here are a dozen such titles: water, Water, Water Everywhere; air, Strictly Fresh; bathing, Dipping Into It; sleep, Morpheus; elimination, Personal Plumbing; walking, Pedaling Alone; teeth, That Murderous Mouth; alcohol, Down the Hatch; cigarets, And the Smoke Goes Up the Chimney Just the Same; pain, The Friendly Enemy; self medication, Medicine Man Tactics; worry, Mental Arsenic.

Dr. Funk gives the impression that he has no intention of saying everything that occurs to him, only enough to arouse the reader's interest and whet his appetite. Thus he is chatty, uses lively words and occasional Fred Allen phrases. Perhaps with his tongue in his cheek he deals with the sex problem in two pages, whereas the teeth get six.

There are no illustrations. The book is easy reading with good type, only 28 lines to the full page. Its purpose is to spread a common sense understanding of some fundamentals in right living. He engages in some kidding of the suckers who chase after commercialized vitamins, scalp restorers, halitosis, headaches, indigestion, obesity, constipation, and fallen arches.

W. W. PETER

Building a Popular Movement—A Case Study of the Public Relations of the Boy Scouts of America
—By *Harold P. Levy*. New York: Russell Sage Foundation, 1944. 165 pp. Price, \$1.25.

Mr. Levy ably describes the policies and methods by which the Boy Scouts of America have become the largest organization for boys in the democratic world. With admirable judgment he avoids administrative details and addresses himself to certain fundamentals which have implications of interest to

every health officer and every leader of a voluntary health organization.

Public health, like welfare, is full of associations and societies that started in fond hopes of becoming "movements," but never quite succeeded in even being efficient office organizations. The urge to create new organizations, rather than utilize old ones, shows itself in the multitude of "block plans," "district health education programs," and neighborhood committees. Derryberry, Marquette, Morgan, and Widemer have tested and developed the strategy of such community and neighborhood plans.

The evidence seems to be that such efforts, public or voluntary, can seldom succeed unless they relate themselves effectively to established media and established community organizations. Competition from organizations of more varied interests, plus public inertia, insure a high mortality for such community plans.

Few people now remember that the Boy Scouts, even with their broad program, met comparable resistances. Their competition was keen, the attraction of militarized rivals was great. The churches were skeptical; an early blunder in policy statement quite properly raised resistance from organized labor.

Mr. Levy describes how the organization built its appeal to its members and an acceptance with the public, an acceptance that in recent years has made early critics leading supporters and troop sponsors. The alert health educator will find many ideas he can transfer or adapt—ideas of policy and strategy, not technics.

This is the second monograph Mr. Levy has produced in the Russell Sage Foundation series of "Studies in Public Relations." The first was on a public agency, the Pennsylvania Department of Public Assistance. Other studies will follow. The Foundation,

then take up the matter of germs, health protection in modern communities, homes, schools, and industry, safety and the human body. It closes with lists and descriptions of good games, food for fitness, weight-height-age tables, considerations of health and advertising and a self testing scale, a glossary and an index.

In general, this is a good book. A general criticism which applies to many portions of the book is that it leaves the reader unsatisfied in dealing too superficially with subjects which it attacks.

There is a lack of accuracy in small matters and this occurs so frequently that it becomes annoying to the well informed reader and may prove a handicap to the teacher. For example, on pages 8 and 9 reference is made to the "United States Social Security Agency." There is no federal agency by such a name. The correct title is "Federal Security Agency."

On page 59 there is emphasis on the "doorknob, book, or money that you touched" with reference to the danger of germs. The possibility of germ transmission through these common contacts is minimized in modern thinking.

On page 61 reference is made to a "tubercular" cow. The correct word is "tuberculous."

On page 62 the statement is made that "many city boys and girls do not know what fresh, unpasteurized milk tastes like." The context suggests that fresh, unpasteurized milk is superior to any pasteurized milk! this is contrary to fact in most localities.

On page 65 a totally inadequate reference is made to botulism; this should either have been omitted or enlarged.

On page 69 there is a gross error, when the claim is made on the behalf of Colonel Gorgas that "his vigorous cleaning of the entire area (Panama)

made it possible for the workers to live without fear of infection." Gorgas failed completely when he relied merely on complete cleaning. It was specific mosquito control that brought success.

On page 75 vaccination and inoculation are referred to as if the two were identical which, of course, they are not.

On page 85 inspection of the Schick test is described as a day after the injection; the actual time is, of course, from 5 to 7 days after.

On page 87 sulfanilamide is referred to as "at first a dangerous drug" as if it were no longer dangerous when unskillfully used.

On page 91 Sister Kenny's method is referred to as "a combination of massage and hot applications"; she has vigorously denied that it is massage.

On page 101 a statement is made that sewage disposal plants have been constructed by sanitary engineers engaged by the health department. Health departments seldom engage construction engineers.

On page 114 milk is called the perfect food which, of course, it is not.

These little errors are not pointed out in a spirit of carping criticism, but because they indicate a failure to do that last careful job of checking which makes the difference between a good book such as this and the outstanding book which it might have been. It would not be difficult in a subsequent edition to correct these shortcomings.

W. W. BAUER

Voluntary Medical Insurance in the United States, Major Trends and Current Problems—By Helen Hershfield Aunet. New York: Medical Administration Service, 1944. 104 pp. Price, \$1.00.

Physicians, public health workers, civic leaders, and others interested in trends of medical insurance in the United States will find one hundred pages of interesting facts and figures

dealing with voluntary medical insurance in the United States in this volume which is small and well written, divided into four parts, one of which is a summary. Part II, entitled "Representative Plans," deals with five group practice plans, one of which is the famous Kaiser plan. A chart on page 26 presents the more significant data with regard to services provided and costs under the five selected practice plans, each of which is discussed in some length.

The growth of the 77 "Blue Cross" hospital service plans during the past decade to nearly 12 million subscribers is attractively presented in table form and should be of much interest to both lay and professional groups that are interested in the future of more adequate medical services.

Commercially sponsored medical insurance group coverage is well treated. Several tables and a chart point out different types of health coverage, such as hospitalization, surgical, medical care, dependants, etc.

The summary deals with general trends of health insurance to cover all medical care expense; however, to date, no complete, comprehensive coverage has been given by any plan—prevention being most often omitted.

J. ROY HECE

Fundamentals of Psychiatry—By *Edward A. Strecker*. (2nd ed.) Philadelphia: Lippincott, 1944. 205 pp. 15 Illus. Price, \$3.00.

The author has assembled a body of fundamental information in compact, readable form which will enable the general practitioner, the medical student, the nurse, and the social worker "to obtain with a minimum of time a workable picture of the field of psychiatry."

The form of presentation follows the standard classifications in terms of etiology and symptomatology as used in

the author's teaching experience. Well selected diagrams and short case studies are used to advantage.

In keeping with present need, chapters 9 and 10, "The Psychiatry of War" and "War Neuroses" should be of interest and use to a broader group than the medical profession alone.

Chapter 11, "The Nurse and the Psychiatric Patient," might well have been addressed to physicians as well as nurses, for we may admit the general medical practitioner too often avoids the responsibility of knowing and understanding the psychoneurotic patient, or even the average patient, as a human being with human emotions which affect his total health.

A brief glossary adds to the general clarity. This little book should help to make the beginnings of understanding psychiatry more simple, acceptable, and interesting.

MARTHA W. MACDONALD

Manual of Human Protozoa with Special Reference to Their Detection and Identification—By *Richard R. Kudo*, D.Sc. Springfield: Thomas, 1944. 125 pp. 29 figs. Price, \$2.00.

This book is based upon the author's notes used in an emergency course in parasitology offered at the University of Illinois. Its viewpoint is practical, giving briefly the essential information for detecting and identifying protozoa of man. Most of the illustrations are original. All of them are drawn in black and white at uniform magnification, 1150 diameters.

The reviewer's chief criticism of this manual, or companion book, is that the figures of the malarial parasites are not in color. This lack greatly lessens its usefulness for teaching and for diagnostic purposes, since the important color characteristics of these parasites in their different phases of development are lost in black and white. Figure 27, showing various blood cells found in

stained blood films, would also have greater value had it been done in color.

It is not likely that any experienced worker will agree to the recommendation (page 53) that feces from suspected cases of dysentery be held in an incubator at 37° C. for later experimentation if an immediate or early examination is not possible. On page 71 the author calls attention to the similarity between coccidian oocysts and the eggs of two worm parasites, *Heterophyes heterophyes* and *Clonorchis sinensis*. A brief statement here as to the importance of knowing the geographical distribution of these parasites and the likelihood of a patient acquiring them would have been a helpful inclusion. Also, it should be pointed out

that these two worm parasites are trematodes, not nematodes, as is stated. Barber and Kowp's method for the examination of blood for malaria is not included. This is an unfortunate omission, since this is now the preferred method and is more generally used by malariologists than the older method described on page 99. It is agreeable to note in this book the retention of the generic name *Entamoeba*, which is obviously correct, rather than *Endamoeba*, the name in common usage in North American publications. The manual is approximately pocket size. It is clearly written, well printed and bound. It will undoubtedly be a much used work of reference.

DONALD L. AUGUSTINE

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Against Vitamin Cure-alls in Milk—Milk is a logical carrier of vitamin D because of its calcium and phosphorus content. Restoring the removed vitamin B's to cereals is a sensible procedure, too. But, concludes the Council on Foods and Nutrition, the addition of extra "B's" and iron and iodine to milk is not justified from the standpoint of public health needs. You'll agree.

ANON. Fortification of Milk with Vitamins and Minerals. J.A.M.A. 126, 7:432 (Oct. 14), 1944.

"The Basic Health of the American People"—Every single man Jack—and lady Jill—among us should read every word of these papers from a panel discussion on "Variations in Industrial Medical Service Plans." You may rub your eyes in amazement when you see such sentences as these: "While industrialists have been willing to assume

their part in the program of medical care, medical societies have been reluctant." "The majority of prepaid medical plans to date have failed and proved totally inadequate." "Experience has demonstrated the unwisdom of initiating a medical society prepayment program on a complete coverage basis." "I think the fee for service basis is definitely wrong in caring for the needs of the people." Altogether, the series is the most wholesome airing of a vital subject that has appeared in a dog's age.

ADAMS, J. M. Stanocola Medical Care Plan (and four related papers). J.A.M.A. 126, 6:333 (Oct. 7), 1944.

Nutritional Deficiency States and Infection—Perhaps the recent demonstration that vitamin deficient animals are less susceptible to certain virus infections will call a halt on the expensive and inadequate way of insuring a

balanced diet via the pill route: so speculate these researchers at the close of a useful paper.

AYCOCK, W. L., and LUTMAN, G. E. Vitamin Deficiency as an Epidemiologic Principle. *Am. J. M. Sc.* 208, 3:389 (Sept.), 1944.

T. A. M. vs. A. P. T.—Seven years' experience with toxin-antitoxin convinced this British M. O. H. that in it he had a stable and reliable immunizing agent. A comparable experience with toxoid leads him to believe it to be a prophylactic of variable potency. Now that toxin-antitoxin is no longer to be available, the "posterior Schick Test" must be stressed, says he. Also he wants an assured immunity in infancy rather than an unchecked initial course with a later "refill."

ANDERSON, A. Diphtheria Immunization. *Pub. Health.* 57, 12:131 (Sept.), 1944.

"Preach and Treat" Found Wanting—This paper is so long that I haven't the will power to wade through it but it ends with this paragraph: "The campaign of enlightenment and early treatment ('Preach and Treat') has failed, and will continue to do so until the public is educated in the methods of early and late preventive treatment and until there is compulsory notification (by numbers and not names) of all these diseases. Enormous sums of money are being spent on enlightenment and early treatment, but why not solve the problem entirely by using a little of it on early preventive treatment and compulsory notification?" Decide for yourself if you need to know the argument.

HARKNESS, A. H. Venereal Disease. *J. Roy. San. Inst.* 7, 10:252 (Oct.), 1944.

Department of Human Behavior—Of the troops served, 15-30 per cent refused any vegetable other than potatoes, as many as half the men failed to eat the entire serving and the uneaten remainders varied from 15 per cent

(tomatoes) to 56 per cent (turnips). The men get precious little vitamin C from this source.

HOPKINS, J. W., *et al.* Statistical Estimation of Vitamin C Intake of Troops in Canadian Army Garrison Rations. *Canad. Pub. Health J.* 35, 10:384 (Oct.), 1944.

Plague—Because it is just a matter-of-fact account of the businesslike way the health officials went about the destruction of rats when plague ridden rodents were discovered in Tacoma, this paper is a pleasure to read. So it is commended to you even though it is quite likely that plague is one disease with which you will never deal.

HUNDLEY, J. M., and NASI, K. W. Anti-Plague Measures in Tacoma, Washington. *Pub. Health Rep.* 59, 38:1239 (Sept. 22), 1944.

Whose Fault?—A horrifying proportion of young American men are found unfit for military service. Who will be the scapegoat, the whipping boy to bear the blame? The schools, inevitably. After removing from the list the mental and physical defects which could not possibly be blamed on our schools, this editorial asks: what is left? This is "anybody's fight" so you may want to get in it.

KEENE, C. H. Editorial. *J. School Health.* 14, 8:202 (Oct.), 1944.

Another Penicillin Victory—It seems that penicillin works with congenital syphilis, too.

LENTZ, J. W., *et al.* Penicillin in the Prevention and Treatment of Congenital Syphilis. *J.A.M.A.* 126, 7:408 (Oct. 14), 1944.

Now You Can Really See Them—Not to be missed are these excellent pictures of bacteria and Rickettsias and viruses, their descriptions, and the discussion which accompanies them.

MUDD, S., and ANDERSON, T. F. Pathogenic Bacteria, Rickettsias, and Viruses as Shown by the Electron Microscope. *J.A.M.A.* 126, 9:561 (Oct. 28), 1944.

Good Job Well Done—You will be impressed by this straightforward story of the epidemiologic study of an outbreak of virulent pneumonitis which originated Heaven-knows-how, and spread by direct contact from fatal cases to nursing attendants. The causative agent was isolated and will be described in a later article.

OLSON, B. J., and TREUTING, W. L. An Epidemic of a Severe Pneumonitis in the Bayou Region of Louisiana. *Pub. Health Rep.* 59, 40:1299 (Oct. 6), 1944.

For the Idly Curious—This is really none of our business, but as a sidewalk superintendent, you may want to know that an army doctor reports 11 of 12 patients with gonorrhea as being cured by one shot of penicillin in a mixture of beeswax and peanut oil (which slows the absorption of the drug).

ROMANSKY, M. J., and RITTMAN, G. E. A Method of Prolonging the Action of Penicillin. *Science.* 100, 2592:196 (Sept.), 1944.

On Being Realistic about V. D.—Even though you may not, at the

moment, be greatly concerned about V. D. or nursing, you should read this paper carefully in order to observe one man at work injecting new life into an old subject. Most professional people are such poor writers that they have much to learn from one who isn't.

SHOSTAC, P. The Nurse in Industry Organizes Against V. D. *Pub. Health Nurs.* 36, 10:302 (Oct.), 1944.

Constructive Medicine? — Dr. Steiglitz offers this term as a preferred synonym for preventive medicine. There *must* be a better term. Please help.

STEIGLITZ, E. J. Constructive Medicine. *Science.* 100, 2597:313 (Oct. 6), 1944.

When Experts Disagree—Suffering, as I do, from an abysmal ignorance of the whole subject, the reading of this lively symposium left me with a conviction that there must be a great deal yet to be learned about rheumatic fever.

WILSON, M. G., and LUBSCHEZ, R. Recurrence Rates in Rheumatic Fever (and four related papers). *J.A.M.A.* 126, 8:477 (Oct. 21), 1944.

ASSOCIATION NEWS

Milton J. Rosenau, M.D., President-Elect American Public Health Association

Dr. Milton J. Rosenau, Dean of the School of Public Health and Professor of Epidemiology at the University of North Carolina, Chapel Hill, was chosen President-Elect of the American Public Health Association at the 73rd Annual Meeting in New York City. Dr. Rosenau was born January 1, 1869, in Philadelphia. He received his medical degree in 1889 from the University of Pennsylvania, and an honorary A.M. from Harvard in 1914. He studied in Berlin, in Paris, and Vienna between 1892 and 1900. Dr. Rosenau served as Surgeon in the U. S. Public Health Service from 1890 to 1909, and for the last ten years of this period was Director of the Hygienic Laboratory (now the National Institute of Health). He was Professor of Preventive Medicine and Hygiene at Harvard from 1909 to 1935, Director of the School of Public Health, Harvard University and Massachusetts Institute of Technology 1913 to 1922, Professor of Epidemiology at the Harvard School of Public Health 1922-1935, Director of the Antitoxin and Vaccine Laboratory and Chief of the Division of Biologic Laboratories of the Massachusetts Board of Health 1914 to 1921. Since 1936 Dr. Rosenau has been in his present position at the new School of Public Health, University of North Carolina.

Among many honors that have come to Dr. Rosenau are presidencies of the American Society of Tropical Medicine, American Society of Epidemiologists, American Association of Immunologists, the American Association of Medical Milk Commissions, the Society of

American Bacteriologists, and the Gold Medal of American Medicine for Service to Humanity, as well as the Sedgwick Memorial Medal which he received in 1934.

MILTON J. ROSENAU, M.D.

Dr. Rosenau is best known for his volume on *Preventive Medicine and Hygiene*, of which the 6th edition was published in 1935. He is also the author of *Disinfection and Disinfectants*, 1901, and of *The Milk Question*, 1912. His principal scientific researches have included the standardization of tetanus and diphtheria antitoxins, the epidemiology of typhoid fever, poliomyelitis, influenza, etc., contributions to anaphylaxis, studies on pasteurization, foot and mouth disease, vaccine virus, and on milk and its rela-

tion to the public health. Dr. Rosenau's bibliography includes more than one hundred and fifty titles.

In his long career, Dr. Rosenau established the first chair of Preventive Medicine and the first School of Public Health, both at Harvard. The Hygienic

Laboratory was the first of its kind on this continent. Exceedingly few writers and teachers in the field of public health are as widely known as Dr. Rosenau. The American Public Health Association honors itself in honoring him.

RESOLUTIONS

The following Resolutions were unanimously adopted by the Association at the Seventy-third Annual Meeting in New York, N. Y., October 3-5, 1944.

1. APPRECIATION

TO DR. STEBBINS AND THE LOCAL COMMITTEE

RESOLVED that the American Public Health Association acknowledges its sincere appreciation to the New York Local Committee and the agencies and individuals represented thereon for their untiring efforts in connection with this Conference.

RESOLVED that the Association expresses its gratitude to Dr. Ernest L. Stebbins, Health Commissioner of New York and General Chairman of the Local Committee, and to the chairmen and members of the several subcommittees for their wholehearted co-operation and assistance in the planning and conduct of this Second Wartime Conference in New York City.

TO NEW YORK CONVENTION AND VISITORS BUREAU AND TO THE HOTEL PENNSYLVANIA

RESOLVED that the American Public Health Association records its appreciation to the New York Convention and Visitors Bureau and to the Hotel Pennsylvania for their splendid coöperation in making available the necessary facilities and space for the conduct of this Annual Meeting.

TO COÖPERATING AGENCIES

RESOLVED that the American Public Health Association extends its sincere thanks to the Public Health Association of New York City, to the National Health Council agencies, to the National Health Library, and to the National Publicity Council for their services in behalf of the Second War-time Conference.

TO THE PRESS AND RADIO

RESOLVED that the American Public Health Association gratefully acknowledges the generous service of the press and radio,

state and local, in carrying the message of the Wartime Public Health Conference to the public.

TO THE EXHIBITORS

RESOLVED that the American Public Health Association expresses its appreciation to its friends and coöperators who have presented such excellent exhibits for the interest and benefit of delegates at this Convention.

2. IN MEMORIAM

WHEREAS, a divine Providence in its wisdom and justice has seen fit to remove from our midst the following members of our Association and,

WHEREAS, by death we have been deprived of the companionship, advice, and counsel of these able and capable members in the Association, therefore be it

RESOLVED that we express our sorrow at the loss that we as members and collectively as the Association have sustained.

Fred Adams, M.B., D.P.H., Windsor, Ont., Elected Member 1914, Charter Fellow 1922.
Alice Ahern, R.N., Ottawa, Ont., Elected Member 1928.

Henry H. Asher, M.D., Manistique, Mich., Elected Member 1938.

Clarence M. Baker, Madison, Wis., Elected Member 1914, Charter Fellow 1922.

Ezra G. Carter, Dr.P.H., Logan, Utah, Elected Member 1924.

John F. D. Cook, M.D., Pierre, S. D., Elected Member 1939.

Walter W. Council, M.D., Juneau, Alaska, Elected Member 1933.

John E. Custis, M.D., Lemmon, S.D., Elected Member 1944.

W. F. Davison, M.D., Kingston, Pa., Elected Member 1930.

Meta DeLoache, Paterson, N. J., Elected Member 1941.

- W. D. Dotterer, Chicago, Ill., Elected Member 1916, Fellow 1942.
- Samuel M. Ellsworth, Boston, Mass., Elected Member 1939, Charter Fellow 1943.
- Charles E. Finlay, M.D., Havana, Cuba, Elected Member 1940, Charter Fellow 1942.
- James V. Foley, M.D., M.P.H., Pocatello, Idaho, Elected Member 1941.
- W. Brownley Foster, M.D., Richmond, Va., Elected Member 1908, Charter Fellow 1923.
- Julia George, Berkeley, Calif., Elected Member 1920.
- Selskar M. Gunn, New York, N. Y., Elected Member 1905, Charter Fellow 1922.
- Paul Hansen, Chicago, Ill., Elected Member 1905, Charter Fellow 1922.
- Olaf Haraldson, M.D., Minot, N. D., Elected Member 1942.
- Mrs. Mary S. Hull, R.N., Santa Fe, N. M., Elected Member 1940.
- George E. Johnson, M.D., Philadelphia, Pa., Elected Member 1934.
- Wilhelm O. Johnson, Springfield, Mass., Elected Member 1939.
- Robert W. Kehr, Seattle, Wash., Elected Member 1934.
- J. H. Kellogg, M.D., Battle Creek, Mich., Elected Member 1878.
- Israel J. Kligler, Ph.D., Jerusalem, Palestine, Elected Member 1912, Charter Fellow 1922.
- J. Leake, M.D., Portsmouth, Va., Elected Member 1933.
- Mary McCormick, R.N., Albany, N. Y., Elected Member 1937.
- James R. McEachern, M.D., Tampa, Fla., Elected Member 1932, Charter Fellow 1936.
- J. J. McShane, M.D., Dr.P.H., Springfield, Ill., Elected Member 1915, Charter Fellow 1922.
- Paul Molitor, Chatham, N. J., Elected Member 1932.
- H. Allen Moyer, M.D., Charlotte, Mich., Elected Member 1939.
- Percy F. Murray, Peabody, Mass., Elected Member 1929.
- Harry B. Neagle, M.D., Providence, R. I., Elected Member 1918.
- J. F. Nickerson, Chicago, Ill., Elected Member 1912.
- John Overton, M.D., Nashville, Tenn., Elected Member 1927.
- M. B. Owens, M.D., Newport, Ark., Elected Member 1931.
- Lillian A. Phelps, Oneonta, N. Y., Elected Member 1943.
- Adrien Plamondon, Montreal, Que., Can., Elected Member 1931.
- Aurelia B. Potts, R.N., Nashville, Tenn., Elected Member 1928, Charter Fellow 1934.
- William M. Randolph, M.D., Charlottesville, Va., Elected Member 1936.
- C. B. Ransone, M.D., Roanoke, Va., Elected Member 1924.
- Armin V. St. George, M.D., New York, N. Y., Elected Member 1934.
- William V. Sanford, M.D., Ripley, Tenn., Elected Member 1930.
- Herman M. Schoberg, St. Paul, Minn., Elected Member 1923.
- Blanche F. Sigman, Copley, Ohio, Elected Member 1941.
- Dr. Rafael Silva, Mexico City, Mexico, Elected Member 1930.
- Robert M. Stith, M.D., Highlands, Wash., Elected Member 1925.
- A. L. Stone, M.D., Camden, N. J., Elected Member 1920.
- Thomas A. Storey, M.D., Stanford University, Calif., Elected Member 1912, Charter Fellow 1922.
- Hassov Van Wedel, M.D., New Rochelle, N. Y., Elected Member 1915, Charter Fellow 1922.
- Lewis W. Waters, New York, N. Y., Elected Member 1937.
- Clifford C. Young, D.P.H., Lansing, Mich., Elected Member 1912, Charter Fellow 1922.

3. SERVING OF NUTRITIOUS MEALS TO SCHOOL CHILDREN

WHEREAS, the serving of nutritious meals to children attending school has been demonstrated to be an important aspect of both the health program and the educational program of the school, and

WHEREAS, the financial ability of a school system to serve adequate meals within the means of the child patrons is likely to be least in those areas in which the nutritional need is greatest, be it

RESOLVED that the American Public Health Association favors aid to school systems to make possible the serving of meals under administrative control and technical supervision by school authorities. Such aid should be conditional on the maintenance of adequate but reasonable standards, providing for safe, wholesome foods combined into nourishing meals, dispensed without profit to the school or any other agency, and served without discrimination between those children who can pay for their meals and those who cannot.

4. CONTINUED ENRICHMENT OF STAPLE FOODS

WHEREAS, the order of the War Food Administrator making compulsory the enrichment of white bread and rolls, the legislative action of certain states with regard to enrichment of certain staple foodstuffs,

and the voluntary action of many food industries have resulted in an improvement in the national dietary with respect to several highly essential nutrient elements, and

WHEREAS, this enrichment in staple low cost foods has been of proportionately greater benefit to the economic groups whose diet is most in need of betterment, and

WHEREAS, the federal order for enrichment of white bread and rolls will terminate with the passing of the war emergency, be it

RESOLVED that the American Public Health Association goes on record as favoring appropriate state and federal action to perpetuate the benefits that have accrued to the national dietary through enrichment of staple foods in accordance with the recommendations of the National Research Council.

5. ADEQUATE COMPENSATION FOR PUBLIC HEALTH PERSONNEL

WHEREAS, the application and administration of public health principles and skills has become a specialty for which special training is required, and

WHEREAS, the safeguarding and improvement of the health of the people have always been primary concerns of the State, presenting opportunities and responsibilities that have attracted and should continue to attract some of the ablest members of various professions, and

WHEREAS, public health workers have often devoted their lives to this field at the cost of such personal sacrifice as inadequate compensation, political interference, insecure tenure of office, lack of opportunity for research or for personal advancement, and

WHEREAS, this Association has repeatedly pointed out the fact that many sections of the country are now without the benefit of any full-time, trained public health workers, and other sections have woefully inadequate numbers of trained public health workers, and

WHEREAS, the post-war period will call for even larger numbers of competent people to safeguard the public health, now therefore be it

RESOLVED that—

1. Adequate compensation and reasonable security in tenure of office will be necessary before public health workers with proper professional qualifications to assume the heavy responsibility of protecting and improving the health of the public will be available in sufficient number to meet the nation's existing and future needs.

2. It is the considered opinion of this Association that health officers and all other specialists in the public health field who have been specially trained for their highly important work should be compensated for their services in an amount comparable with the net income of their professional colleagues in the community.

6. A NATIONAL PROGRAM OF DENTAL CARE

WHEREAS, the public health professions have long sought means to develop a program of preventive dental services, and

WHEREAS, dental surveys almost universally disclose a widespread prevalence of dental disease in the United States, and

WHEREAS, dental disease was the greatest single factor in rejection among selectees at the beginning of the present world conflict, and

WHEREAS, the dental problem requires organized group action for its solution as a part of a general medical care program, therefore be it

RESOLVED that the American Public Health Association endorse and support efforts along the following lines:

1. Research to reduce the incidence of dental disease.
 2. Research and demonstration to develop and test administrative procedures designed to reduce the cost and increase the spread of dental care.
 3. Education of the public in the need of early and continuous dental care to prevent an increasing accumulation of dental defects.
 4. Development of reparative programs, especially for the younger age groups.
 5. Stimulation of health agencies at local, state, and federal levels to secure funds and recruit and train personnel to implement the foregoing program.
- Be it further

RESOLVED that the Executive Board of the American Public Health Association institute such measures as may be necessary for obtaining the above objectives.

7. MEDICAL CARE

WHEREAS, adequate medical, nursing, and dental care for all is fundamental to the health and happiness of the people of the United States, be it therefore

RESOLVED that the American Public Health Association endorse the principle that each health department should feel a responsibility for seeing that within its jurisdiction

an adequate program for such medical care be developed as promptly as practicable.

8. ASSISTANCE TO UNITED NATIONS RELIEF AND REHABILITATION ADMINISTRATION

WHEREAS, the United Nations Relief and Rehabilitation Administration has been entrusted with the responsibility of assisting in the rehabilitation of countries which have been ravaged by the enemy, and,

WHEREAS, one of the principal objectives of this Administration is to restore to full function national health departments, be it therefore

RESOLVED that the American Public Health Association express its full sympathy with this objective and that the Executive Board be requested to seek ways and means by which the Association may assist the United Nations Relief and Rehabilitation Administration in its great task.

9. INTERNATIONAL PUBLIC HEALTH ORGANIZATION

WHEREAS, by the grace of God, the bravery and skill of the military forces of the United Nations are about to be rewarded by complete victory, and

WHEREAS, the promotion of public health in all parts of the world is recognized by all to be of paramount importance to the future happiness and prosperity of mankind, and

WHEREAS, there exists at present no international public health organization whose activities are world-wide in scope, be it therefore

RESOLVED that the Executive Board be requested to bring to the attention of the Government of the United States of America, in the name of the American Public Health Association, the urgent need of immediate planning for the development of such an agency.

NEW FELLOWS OF THE A.P.H.A. ELECTED AT THE 73rd ANNUAL BUSINESS MEETING

Health Officers Section

Samuel D. Allison, M.D., M.P.H., Venereal Disease Control Officer, Territorial Board of Health, Honolulu, T. H.

Will H. Aufranc, M.D., M.P.H., Surgeon (R), U. S. Public Health Service; Venereal Disease Control Officer, State Board of Health, Portland, Ore.

Floyd C. Beelman, M.D., Secretary and Executive Officer, State Board of Health, Topeka, Kans.

Ruth E. Church, M.D., M.S.P.H., Medical Director, Washington County Health Unit and District Health Service 7, Washington, Iowa

Harold M. Erickson, M.D., M.P.H., Assistant State Health Officer, Portland, Ore.

Stanford F. Farnsworth, M.D., M.P.H., Health Officer, Oakland, Calif.

Warren F. Fox, M.D., Riverside County Health Officer, Riverside, Calif.

Donald K. Freedman, M.D., Health Officer, Newport News, Va.

Clifton F. Hall, M.D., M.P.H., Director, Mecosta-Osceola Health Department, Big Rapids, Mich.

Austin E. Hill, M.D., M.P.H., Director of Public Health, Houston, Tex.

Lt. Commander Harold Jacobziner, USN, Acting Sanitation Officer and Quarantine Officer, Norfolk Navy Yard, Portsmouth, Va.

Irvin Kerlan, M.D., C.P.H., Medical Officer, U. S. Food and Drug Administration, Washington, D. C.

James P. O'Brien, M.D., C.P.H., District Health Officer, Northern Health Unit, Woonsocket, R. I.

Major Frank W. Parker, Jr., M.C., Chief, Preventive Medicine Branch, Medical Section, Headquarters First Air Force, USAAF, Mitchel Field, N. Y.

Cecil A. Z. Sharp, M.D., M.S.P.H., Will County Health Officer, Joliet, Ill.

Wilfred N. Sisk, M.D., M.P.H., Director and Health Officer, Buncombe County Health Department, Asheville, N. C.

Hubert O. Swartout, M.D., Dr.P.H., Los Angeles County Health Officer, Los Angeles, Calif.

Jules R. Thebaud, D.D.S., Director General, National Public Health Service, Port-au-Prince, Haiti

Glen S. Usher, M.D., Chief, Bureau of Venereal Disease Control, State Health Department, Trenton, N. J.

Benjamin F. Wyman, M.D., State Health Officer, Columbia, S. C.

Laboratory Section

Luther A. Black, Ph.D., Senior Bacteriologist, U. S. Public Health Service, Cincinnati, O.

Geoffrey Edsall, M.D., Acting Director, Divi-

sion of Biologic Laboratories, State Department of Public Health, Boston, Mass.

Carolyn R. Falk, B.A., Bacteriologist, Department of Health, New York, N. Y.

Stanley E. Hartsell, Ph.D., Associate Professor of Bacteriology, Purdue University, W. Lafayette, Ind.

Nell Hirschberg, Ph.D., Associate Bacteriologist, U. S. Public Health Service, Raleigh, N. C.

Melvin E. Koons, M.P.H., Director, Division of Laboratories, State Department of Health, Grand Forks, N. D.

Malcolm H. Merrill, M.D., Chief, Division of Laboratories, State Department of Public Health, Berkeley, Calif.

Pablo Morales Otero, M.D., Director and Professor of Bacteriology and Immunology, School of Tropical Medicine, San Juan, P. R.

Leslie A. Sandholzer, Ph.D., Associate, U. S. Department of the Interior, College Park, Md.

Anna M. Sexton, Librarian, Division of Laboratories and Research, State Department of Health, Albany, N. Y.

Aimee Wilcox, Assistant Protozoologist, U. S. Public Health Service, Memphis, Tenn.

Vital Statistics Section

Anthony J. Borowski, Dr.P.H., Assistant in Biostatistics, Medical College of Virginia, and Statistician and Chief Clerk, Health Department, Richmond, Va.

Clara E. Cuncell, M.S., Medical Research Officer, Office of Coordinator of Inter-American Affairs, Washington, D. C.

Paul M. Densen, D.Sc., Assistant Professor of Preventive Medicine and Public Health, Vanderbilt University Medical School, Nashville, Tenn.

Exhibit designer, now actively engaged in planning health education exhibits, seeks appointment with responsible organization where ability and experience can be recognized. Competent in supervision. Knows advertising and production. Sound postwar future desired. H-511

NEWS FROM THE FIELD

REORGANIZATION OF PUBLIC HEALTH STRUCTURE IN CANADA

It has been announced recently that the Dominion of Canada hereafter will have three new departments of government replacing the former Department of Pensions and National Health. These will be: (1) Department of Veterans Affairs, (2) Department of National Health and Welfare, (3) Department of Reconstruction.

The Department of National Health and Welfare will be headed by Mr. Brooke-Claxton, a Montreal lawyer who has been serving as assistant to Mr. Mackenzie King, the Prime Minister. The Deputy Minister of Welfare will be George F. Davidson, Ph.D. The Deputy Minister of Health will be Dr. Brock Chisholm, who has served as Director General of Medical Services for the Canadian Army and is a well known psychiatrist.

It is understood that, effective July 1, 1945, the plan has been adopted for grants-in-aid to each child in the Dominion irrespective of financial need. These are to be at the rate of \$5 for children under 6 and \$6 per month for children 6 to 10.

Dr. R. E. Wodehouse, who has served for many years as Deputy Minister of the Department of Pensions and National Health, has been appointed a Commissioner on the Canadian Pensions Board and a consultant in health to the Department of Veterans Affairs.

MASSACHUSETTS CELEBRATES SEVENTY-FIVE YEARS

The seventy-fifth anniversary of the establishment of the Massachusetts State Board of Health, the first in America, is to be celebrated in Boston by an all-day meeting on December 6. The honors are shared by the Antitoxin

and Vaccine Laboratory which was opened fifty years ago.

Among the invited guests were Dr. Thomas Parran, Surgeon General of the U. S. Public Health Service, Brigadier-General James S. Simmons, of the office of the Surgeon General of the United States Army, Dr. C.-E. A. Winslow, of Yale University, Dr. Martha Eliot, of the U. S. Children's Bureau, Dr. Allan J. McLaughlin, formerly Commissioner of Health, Dr. Milton J. Rosenau, of the University of North Carolina, President-elect of the American Public Health Association, Dr. Paul B. Dunbar, Commissioner of the U. S. Bureau of Food and Drugs, and Dr. Reginald M. Atwater, of the American Public Health Association.

The program included a morning meeting at the Peter Bent Brigham Hospital, a buffet luncheon at the Antitoxin Laboratory, afternoon and evening meetings at Ford Hall, and dinner at the Parker House. Dinner guests included Governor Saltonstall, the Health Commissioners of the New England States, Deans of the Massachusetts schools of medicine and public health, and representatives of the American Public Health Association, the Massachusetts Medical Society, and the Massachusetts Public Health Association.

HEALTH EDUCATION FELLOWSHIPS AWARDED

The U. S. Public Health Service has announced that 28 fellowships in health education have been awarded to men and women in 20 states under a new program of the National Foundation for Infantile Paralysis and a continuing grant of the W. K. Kellogg Foundation. The National Foundation maintains 22 of the fellowships. Persons selected

will be assigned to courses in public health at Yale, University of Michigan, and the University of North Carolina. The training will consist of 9 months' academic work and 3 months' supervised field experience. Dr. Parran, in announcing the awards, said that the existing shortage of trained health educators and the demand for expansion of health education activities indicated, both in this country and abroad, the need for qualified personnel with a thorough understanding of both public health and education.

The recipients of the fellowships were announced as follows:

Linnea Anderson, Massachusetts
 Ruth Brossman, Pennsylvania
 Camille Brown, Wyoming
 Theron Butterworth, Louisiana
 Bessie Creecy, North Carolina
 Nell Jane Guthrie, Oklahoma
 Dorothy B. Hamilton, Washington, D. C.
 Dorothy Ann Huskey, Tennessee
 Margaret Idema, Texas
 Marion Jensen, Tennessee
 Maizie Jean Jones, North Carolina
 Rae E. Kaufer, Maryland
 Mary Lou King, Florida
 Mary Evelyn Leith, South Carolina
 Raymond Leonard, North Carolina
 Edith R. Lindly, Oklahoma
 Wilma Mailander, Nebraska
 Jean McCartney, Indiana
 Leila McCormick, North Carolina
 Frances Montgomery, Arizona
 Hazel Mundorff, Nebraska
 Gladys C. Omohundro, Virginia
 Julia O'Neill, Illinois
 Maude Parker, Virginia
 Mary H. Parks, Kansas
 Jeanette Simmons, Iowa
 Louisa Spell, Georgia
 Helen Wilson, North Dakota

CLAXTON APPOINTED CANADIAN
 MINISTER OF NATIONAL HEALTH
 AND WELFARE

Prime Minister W. L. Mackenzie King, of the Dominion of Canada, recently announced in Ottawa the appointment of Brooke Claxton as Minister of National Health and Welfare. Mr. Claxton has been parliamentary assistant to the Prime Minister

and enters the Cabinet for the first time. Among other responsibilities he will set up the machinery for the administration of family allowances.

WESTERN RESERVE OFFERS GRADUATE
 WORK IN HEALTH EDUCATION

Professor James A. Doull of the Department of Hygiene and Bacteriology, Division of Public Health, Western Reserve University Graduate School, Cleveland, Ohio, has announced that students interested in health education as a career and who have had college courses in chemistry, physics, and biology, may be accepted for graduate work after consultation with Dr. Doull, chairman of the department. Basic courses are given in this and other departments in the School of Medicine and in other schools of the university. The laboratories are well equipped and there is an exceptionally good library in the department, supplementing the Cleveland Medical Library, which is on the campus. Practical instruction is under the supervision of Dr. Bruno Gebhard, Associate in Health Education and Director of the Cleveland Museum of Health. Two academic years are required for the Master's degree except for persons with unusual preparation.

NEW YORK STATE ADOPTS CHEESE
 REGULATIONS

Effective November 15, 1944, the New York State Sanitary Code has been amended to prevent the sale of uncured cheddar type cheese made from raw milk. According to *New York State Health News*, the need for this protection is indicated by the occurrence this year of four outbreaks of typhoid fever in the United States and Canada traced to cheese as compared with ten such outbreaks reported during the preceding 20 years. It appears that the unusual demand for cheese and the overcrowding of cold storage ware-

houses, together with the fact that uncured cheese may be sold at the same ceiling price as cured cheese and that the public likes the mild, unripened cheese, has resulted in cheese made from raw milk reaching consumers before sufficient time has elapsed to permit typhoid organisms, if present, to be devitalized.

Unless the cheese itself is subjected to heat treatment equivalent to pasteurization and processing, it is required either to be made from milk, skim milk, or cream which has been pasteurized, or the cheese is required to be ripened or cured at a temperature of not less than 35° F. for a period of not less than 60 days from the date of manufacture. The regulations require the suitable labeling of all cheese sold in New York State.

BAILEY B. BURRITT RETIRES

Mr. Bailey Burritt of New York, N. Y., retired November 1 as Chairman of the Executive Council of the New York Community Service Society. President Roosevelt and other leaders joined with representatives of the nation's health and welfare agencies in praising the career of Mr. Burritt at a testimonial dinner. Mr. Burritt was organizer and director of the Home Service Division of the American Red Cross for the A.E.F. in France during the first World War. He has served with the Community Service Society and its predecessor agency for thirty-one years.

DDT CONSIDERED SAFE FOR INSECTICIDAL USE

Dr. Paul A. Neal, Chief of the Research Section of the Division of Industrial Hygiene, U. S. Public Health Service, reported on November 2 that, in spite of its inherent toxicity, DDT in the desired insecticidal concentrations in air is of such low toxicity that it will not cause injurious effects

in human beings. According to Dr. Neal, the studies conducted at the Industrial Hygiene Research Laboratory of the National Institute of Health showed that DDT in concentrations up to 10 per cent in inert powders for dusting clothes, as in the extermination of lice, offers no serious health consequences. He believed it safe to use as a fly spray. A clinical and laboratory study of three men who had several months of continuous occupational exposure to DDT in its various forms as an insecticide failed to indicate any definite toxic effects from exposure to the drug. In experiments with dogs, daily insufflation of 100 milligrams of DDT per kilogram caused definite signs of poisoning in only one out of the three animals tested after a period of 18 days. Dr. Neal pointed out, however, that massive doses, either by mouth or by skin absorption will cause toxic reactions. Heavy contamination of foods should be avoided. He concluded that, despite the inherent toxicity, the use of DDT in 1 to 5 per cent solutions in 10 per cent cyclohexanone with 85 to 95 per cent Freon should offer no serious health hazards when used as an insecticide.

Major General Norman T. Kirk, Surgeon General of the U. S. Army, reported to the Association of Military Surgeons of the United States at its meeting in New York City on November 3, that DDT had been effective in the control of malaria when sprayed from airplanes at tree-top height. According to Dr. Kirk, DDT will kill adult mosquitoes and flies as well as those in the larval stages when it is used in breeding areas. He reported that Saipan had been a mass of flies and mosquitoes on D Day but that the island was now free of both. He reported that the aerosol bomb kills all insect vectors in closed spaces, particularly the mosquito and fly, and is used extensively to rid airplanes of those

vectors. A 5 per cent solution of DDT sprayed on the walls of barracks, kitchen, or huts will kill all mosquitoes and flies alighting thereon for months after each spraying. He credited DDT with preventing the threatened epidemic in Naples.

NEW PUBLIC HEALTH APPOINTMENTS IN CUBA

It has been announced that Dr. Jose Antonio Presno has been appointed as the new Secretary of Health for Cuba.

Dr. Pedro Nogueira has been appointed Director of Health. Dr. Nogueira was formerly associated with the Rockefeller Foundation.

The Sub-Secretary of Health is Dr. Fernando Lopez.

Dr. Domingo F. Ramos continues as Director of the Finlay Institute in Havana.

NOBEL PRIZES AWARDED FOUR DOCTORS

Announcement was made in Stockholm, Sweden, on October 26, of the award of Nobel prizes in medicine to four scientists, all of them now in the United States, as follows:

The 1944 award in physiology and medicine was made to Dr. Joseph Erlanger, Professor of Physiology at Washington University School of Medicine, St. Louis, Mo., and to Dr. Herbert S. Gasser of New York, N. Y., Director of the Rockefeller Institute for Medical Research. This award covers studies of the functions of individual nerve threads.

The 1943 award was also divided equally between Dr. Edward A. Doisy, Professor of Biochemistry in the St. Louis University School of Medicine and Dr. Henrik Dam of Copenhagen, Denmark, who is now at the Strong Memorial Hospital, Rochester, N. Y. The reward covers studies of these scientists with relation to vitamin K which is concerned in the coagulation of blood.

CONFERENCE OF PROFESSORS OF PREVENTIVE MEDICINE

At the second annual meeting of the Conference of Professors of Preventive Medicine held in New York City on October 2, the following officers were elected:

President, William Harvey Perkins, M.D.,
Dean, Jefferson College
Secretary, Thomas D. Dublin, M.D., Long
Island School of Medicine

Dr. Dublin will welcome suggestions for the 1945 program from qualified workers in the field.

DR. FELIX HEADS MENTAL HYGIENE DIVISION, U.S.P.H.S.

Dr. Thomas Parran on November 1 announced the appointment of Dr. Robert H. Felix as Medical Director in charge of the Mental Hygiene Division in the Bureau of Medical Services, U. S. Public Health Service, Bethesda, Md. Dr. Felix relieves Dr. Lawrence Kolb who retired October 31. Dr. Felix is a native of Kansas, born in 1904, is a graduate in medicine of the University of Colorado in 1930, and was commissioned in the regular corps of the Public Health Service in 1933. He received an M.P.H. from Johns Hopkins in 1942.

DR. SPENCER AWARDED MEDAL FOR CANCER SERVICE

Roscoe R. Spencer, M.D., Chief of the National Cancer Institute, Bethesda, Md., has been awarded the Clement Cleveland Award for outstanding service during 1944 in the effort to control cancer by education. The Palladium medal named in honor of one of the founders of the American Cancer Society, was presented at the annual meeting of the New York City Cancer Committee which was opening a drive for \$100,000 in an annual budget directed toward preventing the death of 40 persons a day from cancer in New York City.

PERSONALS

Central States

STEPHEN C. BRADLEY, M.D., has been placed in charge of the Department of Contagious Diseases of the Terre Haute (Ind.) Board of Health, succeeding the late MAURICE B. VAN CLEAVE, M.D.

ARTHUR V. DE NEVEU, M.D., recently resigned as Medical Director of the Johnston Emergency Hospital, Milwaukee, Wis., to enter private practice; he held the position for 18 years.

ORLEN J. JOHNSON, M.D.,† since August, 1941, Assistant Secretary, Council on Industrial Health of the American Medical Association, Chicago, Ill., has resigned to enter a residency in surgery at St. Luke's Hospital.

ROLL H. MARKWITH, M.D.,* Columbus, Ohio, retired as Director of the Ohio Department of Health on August 21, when his five year term expired, to become Assistant Medical Director of the Clinical Laboratory owned and operated by ANSON L. BROWN, M.D., of Columbus.

LOUIS K. PECK, M.D., has been appointed Health Officer of Crawford, Kankaska, Missaukee, and Roscommon Counties, with headquarters in Lake City, Mich.

CLARKE ROGERS, M.D., Indianapolis, Ind., has been appointed a member of the Indianapolis Board of Health to succeed ARTHUR F. WEYERBACHER, M.D., resigned.

Eastern States

EARL C. BONNETT, M.D., of New York, N. Y., formerly Associate Medical Director of the Metropolitan Life Insurance Company, has been appointed Medical Director of the Company by the Board of Directors. Dr. Bonnett succeeds the late CHARLES L. CHRISTIERNIN, M.D., who died on October 18.

LOUIS I. DUBLIN, Ph.D.,* New York, second Vice President and Statistician of the Metropolitan Life Insurance Company, on October 2 became temporary Executive Officer of the American Red Cross and will serve in this capacity until the return of BASIL O'CONNOR, who is now on an inspection tour of Red Cross operations in France and Great Britain. Dr. Dublin is on loan to the Red Cross for a limited period. His normal assignment is as assistant to Mr. O'Connor, acting as coordinator of the various operating divisions of the Red Cross. In his new appointment Dr. Dublin will devote full time to Red Cross activities.

OSCAR A. DUDLEY, M.D., of Shrewsbury, Mass., Massachusetts Public Health Officer for the Worcester district for 25 years, who was decorated with the Croix de Guerre by the French Government for heroism in the first World War, died on October 28, 1944.

ELIZABETH M. GARDNER, M.D.,* Albany, N. Y., Director of the Division of Maternity, Infancy and Child Hygiene, State Health Department, retired from state service.

EDWARD B. KRUMBHAAR, M.D., Professor of Pathology in the University of Pennsylvania School of Medicine and Graduate School, has been elected an honorary fellow of the Royal Society of Medicine, London, "in recognition of his distinguished services to science."

WILLIAM E. STANLEY,* formerly Professor of Sanitary Engineering at Cornell University, and well known as a consulting sanitary engineer, has been appointed professor in charge of sanitary engineering courses in the department of civil and sanitary engineering at the Massachusetts Insti-

* Fellow A.P.H.A.

† Member A.P.H.A.

tute of Technology, Cambridge, Mass. Professor Stanley recently returned from North Africa where he served as a major in the Corps of Engineers and had assignments as Water Supply Officer for 7 months during the North African Invasion and the Tunisian Campaign and Chief of Construction in the Service of Supply for 8 months.

Southern States

PEYTON M. CHICHESTER, M.D., Assistant Director of Local Health Services with headquarters in Richmond, Va., of the State Health Department, has been named to a similar position at Abingdon to succeed HAROLD M. KELSO, M.D.,† who has accepted a position with the Knoxville, Tenn., Health Department.

LYNN M. GARNER, M.D.,† formerly Health Officer of District Number 8 with headquarters at Higginsville, Mo., has been appointed Director of the Division of Child Hygiene for the State Board of Health, Jefferson City, Mo.

BRIGADIER GENERAL LEON A. FOX,* U.S.A., has been awarded the Typhus Commission Medal for "exceptionally meritorious service rendered first as Director and later as Field Director the United States of America Typhus Commission." General Fox directed the Typhus Control Project of Naples in December, 1943, which brought the epidemic in southern Italy under control within a month.

ROBERT H. FOSDICK, JR., M.D., New Albany, Miss., has resigned as Health Officer of Marshall and Union Counties; he will enter private practice in New Albany.

ROBERT B. GRIFFIN, M.D.,† has been named Director of the Jackson and

Madison County Health Department, Tenn., to succeed LAMAR A. BYERS, M.D., who accepted a similar position in Coos County, Ore.

CHARLES J. GRUBIN, M.D.,† Arlington, Va., has been named Health Officer of Madison County, Ky., with offices in Richmond.

BARBARA HUNT, M.D.,† Meridian, Miss., has been appointed Health Officer of Chickasaw County.

RUTHERFORD O. INGHAM, M.D.,* Johnson City, Tenn., has resigned as Director of the Washington County Health Department. He will be succeeded by MARION G. FISHER, M.D.,† Jonesboro, Tenn.

JOHN P. KENNEDY, M.D.,* recently retired as Health Officer of Atlanta, Ga., a position he held for 43 years. G. P. MORISON, M.D., has been appointed part-time Health Officer of Berkeley County, W. Va., succeeding H. R. DUPUY, M.D.†

JOSEPH T. NARDO, M.D.,† Somerville, Tenn., has resigned as Director of the Fayette County Department of Health to reënter the U. S. Public Health Service.

WARD L. OLIVER, M.D., of Pointe Pleasant, W. Va., Health Officer for District Number 3, has been transferred to Morgantown as Health Officer of Monongalia County. He succeeds WILLIAM B. BAILEY, M.D.,† who was transferred to Norfolk, Va.

MARIE-LOUISE M. PARETI, M.D.,† has resigned as Acting Chief of the Section of Maternal and Child Health of the Louisiana State Board of Health to become assistant to JAMES R. REINBERGER, M.D., Memphis, Tenn.

FRAY O. PEARSON, M.D.,† Director of the Chattanooga-Hamilton County Health Department, Tenn., has resigned to enter private practice and become associated with the Earl Campbell Clinic, effective October 1.

ROBERT E. ROTHERMEL, M.D.,† has been appointed Director of the Har-

* Fellow A.P.H.A.

† Member A.P.H.A.

risson County Health Department, Miss., succeeding HENRY W. KASSEL, M.D.,† who has been assigned to a position in Guatemala City, Guatemala.

WILLIAM P. SCARLETT, M.D., Director of the Division of Venereal Diseases in the Corpus Christi Health Department, has been appointed in charge of the Wichita County Health Unit, Texas, succeeding DAVID F. BRADLEY, M.D., who has been appointed Medical Officer in charge of the State Quarantine Hospital, Corpus Christi.

ELVIRA A. CORRALES-SMITH, M.D., Monroe, La., has been appointed Director of the Arcadia Parish Health Unit.

LLOYD L. TATE, M.D., of St. Louis, Mo., has been named Health and Hygiene Director of the St. Louis public schools.

GEORGE WALDEN, M.D., has been appointed Health Officer of Lincoln County, W. Va., succeeding G. L. McCLELAN, M.D.,

FREDERICK J. WAMPLER, M.D.,* has resigned as Professor of Preventive and Industrial Medicine at the Medical College of Virginia, Richmond, to become Medical Director of the Rustless Iron and Steel Corp., Baltimore, Md.

DON E. WILDER, M.D., Grayson, Ky., has been named Health Officer of Breathitt County.

WALLACE BYRD, M.D.,† Williamstown, Ky., has resigned as Health Officer of Grant County.

WILLIAM L. WRIGHT, M.D., Louisville, Ky., has been placed in charge of the Bell County Health Department, Pineville.

Western States

JACOB C. GEIGER, M.D.,* of San Francisco, Calif., on October 14 received

the honorary degree of Doctor of Science from Tulane University of Louisiana School of Medicine, New Orleans. Dr. Geiger gave the commencement address on this occasion.

DAVID E. SMALLHORST, M.D.,* Glendale, Calif., Health Officer for the San Fernando District, has retired under civil service rules. He has been connected with the Los Angeles County Health Department since 1926.

DEATH

DR. RICHARD V. HENDERSON of the National Institute of Health, Bethesda, Md., died October 20 at the age of 32 while engaged in developing a vaccine against scrub typhus. His death apparently resulted from a laboratory infection.

* Fellow A.P.H.A.

† Member A.P.H.A.

Index of Volume 34, 1944

How to Use the INDEX

This is an Index to all the reading matter in the JOURNAL. It is essentially a title and author Index, although occasional subject headings are provided.

Articles, committee reports, and editorials are listed alphabetically according to the key words in the title, with many cross-references.

Editorials are indexed under "Editorials" as well as alphabetically under the key words in the title.

News notes and fillers are indexed under "News from the Field." This section should be searched as supplemental to the title index.

Matters pertaining to the Association are indexed under "American Public Health Association."

Book reviews are indexed under "Books and Reports."

Obituaries are indexed under "Death Notices."
